question further here, but I have one or two remarks of a practical character to make in reference to operations for cancer. The first great indication in such operations is to remove the disease thoroughly. In lecturing on internal urethrotomy, Sir Henry Thompson insisted on the necessity for cutting through the whole of the stricture, condensing his advice into the maxim "If you cut at all, cut all." Similarly of cancer it may be said "If you excise at all, excise all." In excision of mammary cancer, if a surgeon wishes to be certain that he has acted up to this maxim, he must remove the whole of the gland with the fascia over the pectoral muscle. The investigations of Mr Raymond Johnson and Mr Cecil Beadles have shown that when a nodule of scirrhus exists in the breast the remainder of the gland is by no means normal and may even contain small cancerous nodules at a distance from the primary tumour, at the sternum border, and on the pectoral surface of the gland. Mr Pick tells me that he always cleans the fascia off from the pectoral muscle as he would do in dissecting the part, and this practice will probably now become the rule and not the exception. It has also been pointed out that in reflecting the skin little bits of breast tissue, which come very close to the surface, are apt to be left behind, and that to remove the overlying skin as freely as possible is indicated. Of the axillary glands I have already spoken. The second great indication is to be rigidly economical in the expenditure of the patient's vital fluid, for cancer patients do not bear well any great loss of blood, or, indeed, very prolonged and severe operations. For cases of cancer of the tongue involving the floor of the mouth Sédillot's operation (in which the lower jaw is divided) is an excellent one, as it fulfils all necessary indications. It enables the operator to clear away easily the whole of the disease to which it allows free access and to secure bleeding vessels at once with very little loss of blood. Some of the operations which I performed at the London Hospital by this method were done to render the patient more comfortable, and the subjects of others I have not been able to trace. In 1887, however, I assisted my friend Dr R. W. Goldie, Medical Superintendent of the Poplar and Stepney Sick Asylum, in performing Sédillot's operation on a man who had epithelioma of the tongue. The mass removed was not examined microscopically, but I believe that it was unquestionably epithelial cancer. The patient wrote to me at the end of 1891 to say that he continued quite well and to express his gratitude—partly by an indication of his readiness to receive pecuniary assistance. He has now an enlarged cervical gland and a suspicious swelling near the epiglottis.

The liability to considerable hemorrhage before the linguals can be secured is the chief objection to Whitehead's method of removing the tongue with scissors. The lingual artery may be enlarged in cases of cancer, or may by retraction elude the forceps of the operator. Sometimes it is addicted to emitting a jet of blood directly into the face of the operator and obscuring his view of its orifice. In the majority of cases the hemorrhage is trivial, but there are exceptions, and even in removing only one half of the tongue with scissors after splitting the organ down the middle line, I have experienced a good deal of trouble in securing the lingual. Very free hemorrhage is liable occasionally to occur when the steps of Whitehead's operation have been most scrupulously followed, when they are not and the tongue is removed entire without the successive and regulated pauses for stopping hemorrhage after each snip of the scissors and for ligaturing or twisting each lingual artery in its turn the bleeding may be "terrific" and almost incapable of control. Such hemorrhage infallibly occasions a fatal issue and I feel certain that cancerous patients will not readily bear the loss of the "regulation pint" of which Mr Lund writes in his able *brochure* on Mr Whitehead's operation. It is quite possible but not easy to secure the lingual arteries in the mouth prior to division, but those who resort to antecedent ligature of the linguals, or Billroth's operation, to them in the digastric triangle by the usual semicircular submaxillary incisions.

The most skilful and brilliant operator of our day was

* See Mr Troves case of Excision of the Entire Tongue by Whitehead's Method. THE LANCET April 22nd 1892. It is only right to say that several excellent surgeons prefer Whitehead's method to any other. See Remarks on the Removal of the Entire Tongue with Scissors by the Whitehead Method by Mr Jacobson. THE LANCET April 14th 1893. In a letter to THE LANCET of April 29th 1892, in support of Mr Whitehead's method against the strictures of Mr Troves Mr F. A. Southern of Manchester says that in the majority of cases the amount of blood lost has been very small—certainly considerably less than in

bought to be too little mindful of loss of blood during operations, he did not like or did not consider it needful to stop to secure bleeding vessels, but it is absolutely essential for the welfare of the patients and to obtain the best results that the arrest of hæmorrhage should be a primary care of the surgeon, and that to this he should subordinate thoughts of rapidity and brilliancy. The late Mr Guthrie professed extreme contempt for bleeding arteries even of the second and third magnitude and inculcated amputation at the hip joint without using a tourniquet. He thought that a good surgeon should delight in the recollection of scenes sufficient to try the presence of mind of any man when all his fingers had been engaged in pressing the orifices of bleeding vessels.⁸ What could he have said to the ignoble catch forceps or the elastic bandage! Guthrie's method of amputation at the hip-joint has been practised on one occasion only. The loss of blood, specially from the posterior flap, was so great that no prudent surgeon should repeat the experiment. It is always possible to apply an abdominal tourniquet or elastic tube and to save the loss of blood which would otherwise lead to the early death of the patient.

From what I have now said about cancer it may be gathered that I do not hold in their integrity the current views that cancer is a mere local disease arising from irritation and only spreading both locally and generally by infection from its primary seat. Its development and its recurrence I regard as essentially connected with derangement or incompetency of the organs of sanguification—especially of the liver and the lymphatic glands—and I believe that its occurrence and recurrence will not be entirely prevented, however freely we may remove the disease and tissues which we may regard as precancerous. At the same time, I admit that the value of operations in retarding or removing the disease must be judged not by theory but by the results of the operations themselves. To have a fair chance of permanent success it is clear that operations must be early and complete, and in order that the profession may be able to judge of their real value and validity the whole of the experience of individual surgeons should be recorded as faithfully as has been done, very much to his credit, by Mr Mitchell Banks.

I must now pass on to the abdomen. In former years a wound of the peritoneum was regarded with the greatest apprehension, and surgeons rarely opened the abdominal cavity. When they did it was because they deemed it a matter of necessity, and generally it was a *dernier resort* in intestinal obstruction. As the operation was put off till the last, success could scarcely be expected. In all wounds and injuries to the abdomen the sheet anchor was opium or opium in combination with calomel, which had obtained a reputation beyond its deserts for being able to prevent the effusion and for causing the absorption of inflammatory lymph, thereby preventing and curing inflammation. In rupture of the abdominal viscera the patient was left almost entirely to the unaided efforts of the *vis medicatrix nature*, and, as Billroth has remarked, the *vis medicatrix nature* is a better physician than surgeon.⁹ The morbid dread of even a simple incision into the peritoneum and the admission of air was shown by the reluctance with which many surgeons proceeded to open the sac in a strangulated hernia and the belief that the success of the operation largely depended upon being able to avoid doing so. It is now recognised that the main factor in the results of herniotomy is the condition of the gut at the time of operation. The length of time, however, during which the gut has been strangulated is not a necessary index of the condition of the gut itself, for all depends on the tightness of the stricture. On the one hand I have seen in a case of inguinal hernia a knuckle of bowel quite mortified after only twenty-four hours' strangulation, and I believe that half that time may suffice to kill the gut if the stricture is exceptionally tight, and on the other I have readily reduced by taxis cases of strangulated femoral hernia after the bowel had been down for several days. Two cases occur to me in which I effected reduction after four days' strangulation and both cases occurred about the same period. The first case was that of a lady to whom I was sent by a worthy physician—now, alas no more—who was a pillar of this Society and a very familiar figure at its meetings. He volunteered the statement that I should not be able to effect reduction by taxis and had better not attempt it as after so many days the bowel must necessarily be gangrenous.

The second patient was a man at the hospital, to whom I was summoned by the house surgeon owing to the surgeon on duty being away from home. He told me that he thought I should be obliged to operate and to open the sac. From the want of tension in the tumour in both cases and the comparative mildness of the constitutional disturbance I concluded that the bowel was not tightly nipped in either case, and with very little difficulty and in a few minutes reduction was effected, and both the patients recovered without a bad symptom. At the present day I fancy that surgeons have not the same anxiety to reduce hernia by taxis, and sometimes decline to attempt it where it might be practicable because they consider that the patient is better off after an operation which can be made radical as well as palliative, but I think that it is fairer to the patient to return the bowel—always supposing that it is reducible without any prolonged effort which would damage the gut and be more prejudicial than the knife—unless the state of the case has been fully explained to the patient beforehand and consent has been obtained to a curative operation. If there is any kind of doubt about the condition of the strangulated bowel it should by all means be exposed and examined. Occasionally patients die after taxis either from shock, which is fatal to old people and to patients with bronchitis and emphysema, or because, after being liberated from its stricture, the congested bowel, which, to use Mr Hutchinson's expression, has been triumphantly returned into the abdomen, sets up peritonitis, acting in its morbid state as an infective agent or in a manner which has not been fully elucidated, but which, perhaps, may result from the return of stagnant and altered blood into the circulation.

It cannot be stated too emphatically that the fatality of operations for strangulated hernia is not due in any wise to the operation, but entirely to delay in resorting to it or in calling in skilled surgical aid. Sometimes the little swelling in the groin is overlooked, sometimes the patient falls into the hands of quacks, sometimes the medical attendant or the patient makes too prolonged, energetic and persevering efforts to reduce the hernia by taxis or temporises too long, and a consulting surgeon may be summoned or the patient sent to the hospital only after the loss of the precious time which separates life from death. It is this frittering away of an invaluable time which makes the mortality from strangulated hernia and acute obstruction of the bowels generally still very considerable, and but for this the mortality from strangulated hernia, at all events, might be reduced to a minimum. This result may confidently be looked for as medical education advances. May we hope that it will be an early fruit of the five years curriculum? In the good days coming all practitioners will be guided by the golden rule of examining the sites of hernia in cases of continuous sickness, and of not spending too much time over the taxis, the application of ice or the pursuit of a temporising policy before the case is operated upon. In the earlier years of my connexion with the staff of the London Hospital it was a frequent occurrence to see cases of strangulated hernia in which the bowel had been down for six, seven or eight days and was already perforated, sloughing or gangrenous. Of such cases I had a liberal share. The patients suffered little except from the sickness and died within twenty-four or forty-eight hours after operation, which seemed to exercise a prejudicial effect the free flow of the fæces after division of the stricture appearing to occasion symptoms of exhaustion. The line of treatment of the gangrenous gut then recommended and adopted was to cut into it after relieving the stricture and to fasten the edges to the skin for the purpose of keeping the opening patent and protecting the subjacent connective tissue and fit from contamination by the outflowing fæces. The results were very unfavourable, and though I doubt whether resection of the damaged and dead intestine would have made them better I certainly now think that it would have been the proper method of treatment and that it should be adopted in similar cases.¹⁰

The advantage to the patient in being submitted early to operation for strangulated hernia is twofold. Not only is the prospect of immediate rescue from death much brighter but a radical cure of the local trouble can accompany the division of the stricture without prejudicing the issue of the operation. By a radical cure I mean ligation and removal of

⁸ Lectures on Wounds and Injuries of Arteries by G. J. Guthrie F.R.S. 1846, p. 11.

⁹ Surgical Pathology and Therapeutics p. 167.

¹⁰ See a paper by Mr C. B. Lockwood on this subject Royal Medical and Chirurgical Society's Transactions vol. lxxxiv. p. 199. Mr Lockwood gives a melancholy list of 37 fatal cases of gangrene of intestine being treated by the method referred to at St. Bartholomew's Hospital. Out of 10 cases there were only 4 recoveries. He advocates excision.

the sac and omentum as far as the internal rings of the inguinal, femoral and umbilical canals, combined with such suturing as may be in favour with the operator, but I confess that I place comparatively little faith in deep sutures and think that if they are at all complicated, or if they are metallic and are left buried in the tissues, the patient is much better off without them. I have had occasion to observe that after the canals have been laid open and the sac and omentum ligatured and cut off the vacant canals fill in more or less with granulations, and that if the part is supported with a truss for some time after the healing of the wound till the union is firm and the parts are consolidated a radical cure may be effected without leaving sutures which are permanent and which may act as foreign bodies and become the source of subsequent trouble.

Engrafting upon herniotomy measures for preventing the subsequent recurrence of the hernia do not appreciably add to the danger of the operation. On the contrary, these measures often diminish risk by the removal of an effete sac and unhealthy omentum which would remain as sources of irritation and causes of prolonged suppuration. In strangulated umbilical hernia the benefit of this procedure is well marked. I can remember the dislike which I entertained at one time to being called to cases of strangulated umbilical hernia. The patients are usually obese women with chronic bronchitis and emphysema, whose equilibrium is soon disturbed and who are not favourable subjects for operation. Some, perhaps a majority, of these cases could be reduced with a little patience by the taxis, and I was never anxious to cut them, for the exposure of a mass of altered omentum and the return of the congested bowel usually a portion of the colon, into the abdomen signified consecutive inflammation, suppuration, peritonitis and death. As soon, however, as I adopted a radical procedure and after the reduction of the bowel made a clean sweep of the omentum sac and loose bag of skin the prospects brightened. The resulting wound was small and the patients recovered in much larger proportion, whilst after recovery they found themselves with a level abdomen and in a condition of comfort which they had not experienced for years.

The ancient dread of wounding the peritoneum and the supererogation of fatal peritonitis, which many of us inherited in our medical education, subsided at first gradually and then disappeared with rapid strides. It was seen that clean incised wounds of the peritoneum unaccompanied with extravasation of any kind into the peritoneal cavity, or injury to the contained viscera, as, for instance in stabs of the abdomen, exploratory operations and removal of foreign bodies from the stomach or intestines, were not generally attended with ill results, and that when the viscera were injured the danger arose from extravasation of their contents and not from the implication of the peritoneum itself. The *vis medicatrix nature*, aided to the utmost by calomel and opium, proved so thoroughly unreliable that a bolder course was gradually adopted and sanctioned by professional opinion. A great stimulus was imparted to abdominal surgery by the perfecting of the details of the operations for the removal of ovarian and other removable tumours. The previously high death rate, which had led to strong opposition to the operation in the profession and almost caused its abandonment, was rapidly reduced, and the principles on which success depends were discovered and formulated. It was found that careful cleansing of the peritoneum after operation was all important and that to leave blood or serum or other decomposable fluid behind meant peritonitis, constitutional disturbance, septicæmia from absorption of decomposed fluid, and a fatal issue to the case. The *toilet of the peritoneum*, carried out differently in detail by different surgeons, is now a cardinal feature of the operation and has been found applicable to cases of suppuration rupture of cysts, perforations of the hollow viscera and extravasations from injury and disease with equally beneficial results. Reopening the peritoneum and making a second toilet is often practised with great benefit if the case is not doing well. Another cardinal point in abdominal surgery has been established through the observation made in experiments on animals that two peritoneal surfaces when brought into close approximation rapidly and firmly unite, and to this principle, which is now applied in all wounds of the hollow viscera whether caused by accident or inflicted by the surgeon himself, the profession and mankind are indebted for many of the brilliant achievements in abdominal surgery at the present day. Thus the peritoneum, instead of being regarded as an enemy to the surgeon and to the patient, is now looked

upon as their best friend when properly treated and understood. Hence have sprung other changes in practice in the last few years. Operations founded on the principle of avoiding and, as it were, circumventing the peritoneum, such as lumbar nephrectomy and nephrotomy and lumbar colotomy, are rapidly yielding place to a considerable extent to the direct or dia peritoneal¹¹ method of procedure. Dia peritoneal nephrectomy and nephrotomy, with precautions, of course, to prevent the entrance of injurious fluids into the cavity and their retention therein, as well as inguinal colotomy, are largely superseding the retro-peritoneal operations. It is recognised that it is far better to make an intentional and clean cut into the peritoneum in front than to wound it or tear it unintentionally and surreptitiously behind. The same influence and change are extending to the ligature of the common iliac, internal iliac and external iliac arteries, but for the external iliac artery, at least, I think that the subperitoneal method is quite satisfactory and much to be preferred.¹² A more efficient medical treatment of peritonitis following abdominal operations is now becoming established. Former students and house surgeons at the London Hospital will remember that Mr. Luke alone amongst the members of the surgical staff prescribed the cathartic saline mixture instead of tincture of opium after an operation for strangulated hernia. I believe that Mr. Luke had reason on his side, and that the sulphate of magnesia reduced the distension of the intestines above the stricture which the routine treatment of opiates tends to maintain. I learn from Mr. Greig Smith that Mr. Lawson Tait makes frequent use of saline purgatives, and where others would drain he purges. Mr. Smith himself is a strenuous advocate of the value of saline purgatives in place of opium and sedatives as a remedy for distension and peritonitis. "A purge," he says, "carries off great quantities of gas and fluid, relieves the distension, and probably, by its physiological action, relieves engorgement of intestinal vessels." A Seidlitz powder or a dose of Epsom salts will sometimes act like a charm in these cases, putting an altogether new complexion on the case.¹³ The therapeutic value of purges in operative peritonitis is also well known to American surgeons, and to Professor Gyll Wyhe, who gave no opium in 1886, but in variably, on the appearance of distension, pain and vomiting, administered enemata and purgatives with the most signal advantage. "I am convinced," he says, "that, in my own experience, I have seen many lives saved, besides a vast diminution of the trouble and difficulty in managing cases afterwards."¹⁴

So far as abdominal disease is concerned the technique of the operations now performed for affections of the liver, gall bladder, spleen, pancreas, kidneys, stomach, intestine, rectum, bladder, ovaries and uterus leaves little to be desired. Scarcely one of these operations was in vogue when I was a student. It may also be noted that the physician of the present day is often more surgical than the surgeon himself, and more keen in recommending the surgeon to perform an operation than the surgeon is keen to perform it, but cases there are, such as those of *intestinal obstruction*, where earlier consultation with the surgeon would be beneficial to the patient. I say this from a recollection of one or two cases which had remained in the medical wards for two or three weeks and were then transferred to the surgeon for the performance of colotomy at the eleventh hour. I say it also with a full knowledge of the great benefit which occasionally accrues from medical treatment and also from kneading the abdomen. I can recall four or five cases in which kneading the abdomen removed the symptoms of obstruction, and all were cases which seemed likely to be capable of relief by operation alone. Time will not permit of their introduction here, and I must limit my remarks to a few conditions in which greater surgical activity may lead to the rescue of future sufferers from inevitable death.

The advisability of operating where practicable in cases of

¹¹ The term dia peritoneal is etymologically more correct than the terms retro peritoneal, intra peritoneal, extra peritoneal, and sub peritoneal, which are hybrids, and have become acclimatised. Ecto-peritoneal would be more correct than retro-peritoneal.

¹² In THE LANCET of Dec. 10th, 1892 I am credited undeservedly with a dia peritoneal ligature of the common iliac artery. My colleague Mr. Treves, ligatured the internal iliac in this way for a necrosis of the hip-joint with marked temporary benefit (Clinical Society of Transactions vol. xxv, p. 249). Perhaps this is the operation which the writer in the Mirror of Hospital Practice had in his mind when he said that "the operations on the common iliac of Dennis in America and of Rivington and Lucas in this country have led to the fuller consideration of this subject." I make this correction as I do not wish to appear like the jackdaw in borrowed plumes. Two cases of ligature of the external iliac artery which I published were done by the sub-perit. neat method.

¹³ Abdominal Surgery by Mr. Greig Smith, pp. 92 and 94.

perforating ulcer of the stomach and even in *perforating typhoid ulcer* is recognised at the present day. A few cases have been submitted successfully to operation, and I am led to inquire whether surgical interference in cases of obstinate ulcer of the stomach might not be beneficial at an earlier date. In other words, could not the operation be undertaken for the prevention of perforation rather than for endeavouring to save the patient after perforation has occurred? "From a surgical point of view," says Mr Greig Smith, "it is important to note that the perforating ulcer lies, in the large majority of cases, in the anterior wall of the stomach. Dreschfeld says that the ulcer perforates on the anterior surface eighty five times out of 100 cases, whilst on the posterior surface only two and in the pylorus only ten, out of 100 perforate" (*op cit*, p 773). The difficulty, therefore, in dealing surgically with ulcers on the anterior surface of the stomach is chiefly confined to diagnosis and prognosis, but ulcers on the posterior surface come into a different category, it might be necessary to incise freely the anterior surface of the stomach to deal with them satisfactorily and surgical difficulties would be added to those of a strictly medical character. On the posterior surface of the stomach the mischief occasioned by perforation may for a time be lessened by adhesion of the stomach to the front of the vertebral column. Some years ago a housemaid in our family about twenty three years of age suffered from severe gastric symptoms which appeared to me to point to chronic ulceration of the stomach. She had pain in the right hypochondrium both in the early morning and five minutes or so after taking food. The pain lasted about ten minutes and was relieved by eructation. After eating pain was experienced in the back—a very important symptom—and she brought up her food again. There was no hæmatemesis, but often on rising in the morning she had sudden pains in the stomach and brought up half a pint of watery fluid. When she went about the house she used to bend her body forwards—a symptom which I have not seen noticed in medical works. The patient was placed under the care of Dr Fenwick and was admitted into the London Hospital. After some weeks she died and the post-mortem examination revealed chronic perforating ulceration of the posterior wall of the stomach. The vertebral column and superjacent structures to which the stomach was adherent, supplied the deficiency in the viscera itself. Is it possible to diagnose and treat surgically a condition of this kind?

Ruptures of the stomach seem generally to be quickly fatal—so quickly that there is scarcely time for the surgeon to operate. In the latter part of 1886 I had a case under my care which I believed to be rupture of the stomach complicated or uncomplicated with rupture of the liver or spleen. A boy aged thirteen a porter had been violently squeezed in the abdomen, and was admitted into the London Hospital in a state of collapse—pale, conscious, restless, respirations shallow, the pulse rapid and small and soon becoming imperceptible at the wrist, the pupils equal and mobile. When I saw him soon afterwards his face had a cyanotic aspect and there were marked tenderness and pain in the epigastric region. After examination I came to the conclusion that probably the stomach had been ruptured. Unfortunately he was evidently moribund and it was impossible to explore. He died very speedily and no necropsy was made.

Ruptures of the intestine are rather more hopeful and Mr Croft has operated on them with success.¹⁴ In 1886 a case came under my care at the London Hospital which would have been a most favourable one for surgical interference, but in which I was deterred from operating owing to a doubt as to the diagnosis arising from absence of nausea and vomiting noted as almost invariable and most distressing symptoms of the injury. A carman aged forty one was admitted into the London Hospital on Feb 3rd, 1886. He had been struck in the abdomen just below the umbilicus by the shaft of a waggon and had been jammed against a wall. He complained of great pain at the umbilicus and lower part of the abdomen, his face was anxious, his lips were pale, the pulse was frequent, but remarkably good, there was no vomiting or retching and half an ounce of brandy given was not returned. Sixteen ounces of clear normal urine were drawn off. In the course of the case the abdomen became a little swollen and very tender on pressure at one particular spot near the umbilicus. The pain and tenderness at this spot continued till death. The temperature rose to 101° 3 on the second day and to 101° on the third day,

being normal afterwards. The pulse on Feb 3rd was 126, but not small or too compressible, the respirations were 24. The bowels were confined, but on the fourth day were opened by an enema, with some relief to the pain. No blood passed per anum. There was never any vomiting or retching or complaint of feeling sick during the whole course of the case. The accident happened at 4 P.M. on Feb 3rd, and the patient died rather suddenly at 12.25 A.M. on the 8th, he thus lived four days, eight hours and twenty five minutes after the accident. He was treated with one-third of a grain of morphia every eight hours, had ice to suck, and took milk and brandy in small quantities without returning them. The treatment consisted of Leiter's tubes containing iced water applied to the abdomen. Necropsy. On opening the abdomen a quantity of liquid fæces mixed with lymph flowed out. A portion of the small intestine situated in about the middle of the ileum was found ruptured cleanly, completely and circularly, the ends had been nearly in apposition, but there had been considerable extravasation of fæcal matter. The coils of the intestine were partly matted together by lymph.

In the foregoing case the chief symptom was the tender swelling with the fixed pain near the umbilicus, and I could not persuade myself that the intestine itself had been ruptured owing to the absence of nausea and vomiting, even after the patient took milk and brandy. This condition of things deterred me from operating. The necropsy was made by Dr Sutton, to whom my regret at not having explored was communicated and he said to me, "I hear that you are sorry that you did not operate in this case—you need not regret it, for you could not have done anything for the patient." With this consolatory observation I could not concur as the case was as favourable for operation as any we are likely to meet with. The value of fixed pain at one spot as indicative of ruptured or ulcerated bowel was exemplified in another case in which the intestine gave way by ulceration two or three weeks after a successful herniotomy. A man between thirty and forty years of age (if I rightly remember for I have not yet found the notes) was admitted for a strangulated left inguinal hernia, congenital and accompanied by retained testis. The sac and testis both lay outside the abdominal ring. On this I operated, removing the sac and testicle with the cord as high as the internal abdominal ring. The patient recovered quickly and the wound had healed when after a visit from friends who brought him forbidden luxuries he was seized with a pain in the abdomen and soon developed serious symptoms. He had marked pain and tenderness in the hypogastric region. I suspected that ulceration of the bowel had occurred and had a consultation with a senior colleague, who dissuaded me from interfering. The patient shortly died in a state of collapse, and exactly under the seat of pain the knuckle of intestine which had been in the hernial sac was found ulcerated and perforated. At the seat of operation the left inguinal canal was obliterated though no sutures had been used the peritoneum passing in an unbroken plane over the internal ring. In fact, there was a radical cure without suturing.

Here then, we have two cases in which fixed local pain and tenderness existed at the site of a breach in the intestine, and I think they teach us that we ought to explore under such circumstances when the rest of the history supports the probability of a rupture or perforation. Another condition which it ought to be within the resources of science to remedy is *rupture of the mesentery*. Three cases have come under my observation. In the first case, which occurred a good many years ago the injury was detected on the post-mortem table, and as I have not the notes of the case I cannot give the particulars. The other two cases were associated with hernia.

On Oct. 25th, 1886, a young man aged twenty six was admitted for a strangulated right inguinal congenital hernia. He had had the hernia for nine years and had worn a truss. In addition to the usual symptoms of strangulation he displayed marked signs of depression and collapse, although the hernia had only been down a few hours. About 1 P.M. I was sent for and met my colleague, Mr Reeve, on the steps of the hospital, and he assisted me at the operation, taxis under the anæsthetic not proving successful. On opening the sac some blood and bloody fluid were let out. The structure was at the internal ring and was readily divided with a guarded bistoury. Some omentum which lay in the sac was ligatured and excised and the congested intestine returned. As soon as this had been done blood began to flow down the canal, and it was difficult to determine its source. The omental stump a hepatic vein, and an abnormal epigastric or other artery crossed

¹⁴ Clinical Society's Transactions vol. xxiii. p 161.

the sac were thought of, but the bleeding did not come from any of these. I brought down the previously strictured intestine which lay near the ring and examined it, and the bleeding stopped. It did not occur to us to pull the intestine down further and look at the mesentery. On returning the intestine and leaving a clear passage the bleeding recommenced. The only course seemed to be to open the abdomen, and this was done by an incision between the umbilicus and the pubes. It was soon found that the bleeding came from a laceration of the mesentery. A large vein was ligatured, the effused blood removed by sponging, and the wound closed. Peritonitis supervened, and the patient died on Oct 29th, the fourth day. That the laceration of the mesentery had taken place before the patient's admission was indicated by the collapsed state of the patient and the blood in the sac. I have never found blood in the sac in any case of strangulated hernia where taxis has been applied in the hospital only. In this case it is right to mention that taxis was applied three times in the hospital—once in the receiving room, once in the wards after the application of ice and once by myself, but I do not think any of these efforts could have produced the laceration. The cold, clammy skin, the very feeble pulse and extreme abdominal pain on admission pointed to an antecedent cause. In the second case the mesentery was ruptured by contusion of an inguinal hernia.

Another carman, aged fifty three, was admitted on the morning of Jan 19th, 1887, complaining of great pain around the region of an old right inguinal hernia and in the abdomen generally as far as the external ring. The rupture itself was down and about as big as the fist. The patient had been jammed between a cart and a brick wall, his inguinal region and right ileum being the parts where the injury was most severe. There was a graze over the sacrum. So great was the tenderness over the rupture that the patient could not bear to be touched. His pulse was weak and quick, his temperature 100° 5'. In the early afternoon I visited the hospital, saw the patient and decided at once to explore, remembering a case which I had seen some years previously in which the intestine in a reducible hernia was ruptured by a squeeze or blow. On opening the sac a quantity of blood gushed out and the small intestine which it contained was found to be torn away from the mesentery. There was considerable difficulty in arresting the hæmorrhage from the various vessels which had been ruptured. The intestine itself was black and cold. On considering all the circumstances of the case, I decided to leave the involved intestine in the canal close to the surface of the wound and to allow nature to establish an artificial anus. Iodoform and cotton wool were applied to the wound. On the following day the patient experienced great tenderness in the abdomen and could not bear any pressure. There was tenderness also in the testicles, and there was ecchymosis in the perineum and scrotum. The temperature was normal, but the pulse was extremely small and rapid. He died in the afternoon from heart failure, due to acute peritonitis. The necropsy disclosed old and recent peritonitis.

In the foregoing case I might have resected the portion of intestine from which the mesentery had been torn, and I have no doubt that this would usually be the best practice to adopt. *A priori* it might have been expected that the free anastomosis of the intestinal vessels would have enabled a small portion of the intestine deprived of its mesentery to retain its vitality, but this separation for only a short distance is incompatible with the life of the part. Mr Greig Smith writes "In experiments on animals Rydygier and Madelung showed that gangrene was liable to occur in pieces of bowel protruding beyond the mesenteric attachment. Zesas, continuing and extending these experiments, found that gangrene always followed separation of the mesentery close to the divided bowel, but that no such result followed when the separation was made at a distance."¹⁵ In rupture of the mesentery a deleterious influence must be exercised by the effusion of blood into the peritoneal cavity, and the entrance of air in abdominal section or herniotomy must render the blood liable to decompose. To make an operation for ruptured mesentery complete, free irrigation of the peritoneum with warm water or a mild and warm antiseptic solution would probably be the proper course to adopt. For this purpose when the ruptured mesentery is found in a hernial sac it would be necessary to open the abdomen and wash out the peritoneum till the fluid came out quite clear. This step would prolong the operation and make it perhaps rather more

serious but it seems to me the best treatment to adopt, and irrigation of the cavity with water at a temperature from 100° to 110° has been found to be preventive of shock. Surgical text-books do not treat fully of this accident or the best mode of dealing with it.

Before concluding I wish to say a few words about *rupture of the urinary bladder*. Nearly ten years ago I published a work on this subject embodying papers which had been read at this Society. The book was written partly for the purpose of showing the futility of the ordinary treatment of the injury by catheterism &c and the advisability of performing abdominal section in cases of intra peritoneal rupture if the patients were to have a prospect of being rescued from almost inevitable death. At the time I wrote only two cases had been recorded in which this treatment was pursued—Mr Willett's and Mr Heath's. Both were unsuccessful chiefly because the method of suturing was defective. Both these surgeons brought the edges of the rent together, for at that time Lambert's suture was not in vogue, although Lambert introduced it in 1825 or 1826. In my monograph I quoted Vincent's plan of bringing serous surfaces together, but I am sorry to say that I did not then know its supreme importance. If I had, I should have insisted on the employment of this method, and this method alone. Having observed and been the first to point out that the edges of a bladder rent are often lacerated and contused, I thought that possibly if the edges were pared before being brought together they might unite better, possibly by first intention, and success be thus obtained. Hence, both in my monograph and in the article on Rupture of the Bladder in "Heath's Surgical Dictionary," I mentioned it in a tentative way. In my monograph I said "Whether the rent in the bladder should be sown up or not, with or without paring the edges, must be left to be decided by future experience." At the end of 1886, about two years after my work appeared, Sir William MacCormac published two cases of intra peritoneal rupture treated successfully by abdominal section, Lambert's suture having been used in each case. In 1887 Mr Walsham and Mr Holmes each had a successful case in which the same procedures were adopted. In reporting their cases both Sir William MacCormac and Mr Holmes referred to my tentative suggestion about paring the edges. Sir William MacCormac said "In ordinary traumatic cases of intra peritoneal rupture of the bladder the margins of the rent are generally lacerated in appearance and soon become swollen. Rivington recommends paring these edges off, but when they are fully inverted by the method of suture paring becomes unnecessary and needlessly adds to the difficulty and duration of the operation."¹⁶ Mr Holmes said "Paring the edges of the rent which Mr Rivington speaks of should be entirely reprobated."¹⁷ Both these excellent surgeons overlooked the fact that my suggestion as to paring the edges was made only in reference to the practice of uniting the edges of the rent as practised by Mr Willett and Mr Heath, and for that purpose I believe that it might have been a helpful suggestion. The fortunate introduction of Lambert's suture which was a main factor in securing success for abdominal section in cases of intra peritoneal rupture of the bladder, of course, superseded the basis on which my suggestion was made.

On one circumstance I may be allowed to feel great gratification. A Scotch critic of my work remarked that the chapter on treatment was the shortest in the book and that the treatment which I recommended for intra peritoneal rents might be summed up in one word, "laparotomy." It was necessary at that time to insist very forcibly on abdominal section and removal of the pints of effused urine as the only means of salvation, and I rejoice at the great success which has since attended this course of treatment even after the lapse of a longer interval than appeared to permit of it.

After a critical examination of all the reported cases of recovery after intra peritoneal rent by the *vis medicatrix naturæ* aided, perhaps, by catheter, irrigation and aspirator, I could not find one unequivocal case, and to day I wish to repeat the conviction in this modified form—viz., that there is not on record a single satisfactory case of recovery from the ordinary traumatic intra peritoneal vertical rent on the posterior surface of the bladder, varying from an inch to three or four inches long and admitting the urine contained in the distended viscus freely into the peritoneal cavity. Mr Morris's unique case does not come into this category. After

no-book appeared, the late Mr Cock put on record a supposed case of recovery after intra-peritoneal rupture, the subject of the accident being an elderly gentleman. The basis of the supposition was the fact that the patient had not passed urine for several hours before he recovered the blood in the hypogastric region, and it is consequently taken for granted that the bladder was full. There is no record of the patient having taken anything to drink since he last passed urine. His medical attendant passed a catheter but did not draw off any urine, and he concluded that the bladder was empty. The next day Mr Cock was called in and drew off readily from the bladder half a pint of urine, almost clear and even injected warm water and recovered the whole of the fluid. The patient made a rapid recovery save that he lost the power of voluntary micturition. That the bladder or its immediate vicinity had been contused is evident, and an effusion of blood occurred in the hypogastric region, but I think it is equally clear that if there was any rent at all it was not a rent into the peritoneal cavity. For the future, at all events, we may fairly hope to be delivered from fictitious claims of this kind, because Mr Christopher Heath has pointed out and employed a ready method of detecting a rupture—namely, by injecting the bladder. This method I employed in February 1880 in a case in which my house surgeon suspected that an intra-peritoneal rupture of the bladder had occurred. The particulars I must reserve for the second edition of my work, but I may say that I put the patient under an anæsthetic and injected twenty ounces of warm boracic solution. All the fluid was recovered nearly clear. It contained a small blood clot and it was ascertained that the bladder was whole but that the urethra was suitably torn.

It will be gathered from what I have said in regard to abdominal lesions that I advocate an earlier and a bolder treatment in certain conditions which can only be remedied by operative measures. I do not advocate indiscriminate exploration or abdominal section on moribund patients but exploration founded on a full consideration of all the facts and a reasonable probability that there is present a lesion which may prove capable of relief by operation. And I conclude with the words of Nathaniel Ward to the Hunterian Society in 1854: 'By scrutinising what we have done we come generally to know what to keep doing; treatment conducted on sound principles urging us to confidence, and treatment deviating from them warning us to caution.'

THE NERVOUS SYSTEM IN CHILDHOOD

By WILLIAM GAY, M.D. EDIN. M.R.C.P. LOND. &c.
LATE CLINICAL ASSISTANT HOSPITAL FOR THE PARALYSED
AND EPILEPTIC QUEEN-SQUARE.

DR. MEECIE has descended in *Bacon* in a graphic and picturesque manner the differences which in his opinion exist between the nervous system of a child and that of an adult. Briefly expressed, his main contention would seem to be this. At the time of conception a certain amount of energy is implanted in the individual, and it is by the gradual withdrawal and utilisation of this that the evolution and maintenance of the body are accomplished. It follows from this that the amount of energy available at any given time is in inverse proportion to the age and the child has not only a much greater amount of energy stored up than the adult, but it is nearer at hand—in other words it is more easily evoked. This abundance of energy readily accounts for the frequency of convulsive disorders during infancy and for the common occurrence of hysteria and similar affections at the period of puberty. The infrequency of insanity during childhood is explained by the fact that the lowest strata of the nervous system, which only in the child are fully developed, are rendered most stable because they are evolved at a time when the greatest amount of energy is available. From the foregoing considerations it follows that certain things being the same, the length of life is longer or shorter in proportion to the initial amount of energy possessed, and to that Dr. Meechie looks for the explanation of the fact that children have greater powers of resistance than the parents. The very simplicity of this theory renders it very seductive.

and there is no doubt that, if true, it readily explains the very striking peculiarities and tendencies of the child's nervous system. But it seems to me that it does not go far enough—that a step is missing and for the following reasons. Whilst admitting that the *potential* energy of a developing individual is greater than that of the same arrived at adult life, it is difficult to conceive how during boyhood there is a greater expenditure of *actual* energy than during manhood. Consider the life history of a boy and that of a man. Compare his restricted environment, his narrow range of passion, his limited pursuits with what obtains in the adult, and it is scarcely credible that, even though a considerable amount of energy be used up in the evolutionary process, he consumes a greater relative quantity at any given time. Inasmuch, too, as the boy has greater powers of resistance than his father on account of the greater amount of energy available, it follows that the new born infant, with still greater energy at hand, has superior powers of resistance to the boy and by so much more than the man. This is clearly impossible. So far therefore, as concerns the expenditure of actual energy it would seem as if there were a gradual crescendo up to the time of perfect development, then possibly a stationary period, and then a diminishing down to the time of death.

At the risk of appearing prolix, I shall briefly mention some accidents in the life history of a child which have a certain bearing upon the elaboration of an alternative theory. At the time of birth the various nervous processes subserving nearly all the organic functions of the body are in a state of complete development (though as will be subsequently seen, they are not fully controlled). For this reason they are little liable to functional derangement, and it is only at a later period, when they become represented in higher levels of the brain and are influenced by emotion, that any of them are subject to disturbance. The physiological processes of organic life are practically the same in the infant and adult and though the heart and respirations decrease in frequency with advancing years a reason for this will be suggested later. In regard to the muscular apparatus although each muscle is capable of being put into action there is a complete absence of co-ordination, except in those muscles associated with the organic functions—e.g. respiration. Dr. Hughlings Jackson regards the brain as made up of three evolutionary levels: the lowest of which corresponds roughly with the basal ganglia and centres below, the middle with the motor area, and the highest with the pre-frontal region of the brain. Adopting this nomenclature it is recognised that at birth the lowest level, comprising the medullary centres and those representing the simplest combinations of muscular movements is in a state of almost complete development. One function that of the salivary glands is not developed until some months after birth, and it is instructive to notice that some protection is then needed on account of the excessive secretion of saliva. About this period convulsive disorders of all descriptions become very common, and in this connexion it may be noticed that twitching of individual muscles in the hands and feet often occurs during sleep. The sphincters although acting normally are not fully under control until some months after birth and are in many cases inefficiently controlled at night for many years, and in a certain number of cases by day also. Night terrors and somnambulism coincide with the evolution of mental processes and the various expressions of hysteria and chorea first make their appearance after the development of the emotions. Functional nerve disorders are thus extremely common during infancy and childhood and are easily evoked. The evolution, whether it be of function, muscular action, mental processes or of emotion is accompanied with a liability to disturbance. At a later period of life the exciting causes of these affections would be altogether ineffectual in producing the same results.

Why is it that the course of development is characterised by instability? It is hardly necessary to prove the existence of some such function as inhibition, for it is impossible to conceive how the various nervous processes of the body could be carried on for a moment without it. Life would consist of a single prolonged convulsion. Everything goes to show that every nerve centre from the simplest and lowest to the highest and most complex, is in a condition of health efficiently controlled. The nervous mechanism under any particular function of the body should respond to its appropriate stimuli and to these alone and to no other the means must be provided to keep the system adequately in check. When the nature of inhibition is done

¹ Guy's Hospital Reports, 1881, Serpiginous Pustules, &c.
² Memoir on Strangulated Hernia, 1884.

not matter here, it is sufficient that it exists. It has been proved that certain centres—e.g., the urinary—are again represented at a higher level of the nervous system from which they are controlled. It seems probable that the higher strata of the brain generally not only represent certain functions in themselves, but control the centres of an inferior level in addition. In this way is constituted the so called "hierarchy" of the nervous system, a term which implies that the centres are arranged in such a manner that they are not only of increased functional importance the higher the position they occupy in the nervous economy, but that they have additional duties to perform in the way of dominating and regulating the centres of inferior degree. As a rule, therefore, the lower the centre the more fully is it under control, the more stable does it become, and, as Dr Mercier points out, a further reason for this increased stability of the lower centres is to be found in the fact that they are developed at a time when the available energy is the greatest. If it were not that some of them at a later period are again represented at a higher level of the brain and are brought under the influence of certain emotions, they would scarcely be liable to any functional disturbance. In this way I have endeavoured to explain the nature of laryngismus¹ and that convulsions even are occasionally due to fright. The desire to micturate under the influence of fear is an example of the loss of inhibition of the urinary centre when under emotion. The heart for the same reason beats more rapidly, illustrating a deficiency of vagus inhibition. That the motor apparatus is similarly influenced is shown by the history of chorea and tremor of the hands, so often the result of fear. These considerations go to show that, although the lower centres in the child are fully controlled, they are subject to disturbing influences as soon as the emotions are developed. These indeed imply a want of psychological control of which the former are the physical expressions, and the exact seat of the resulting discharge depends upon the relative stability of the various centres. Inhibition thus plays a part of the first importance in the development and maintenance of the nervous system. By means of it the various functions of the body are adequately regulated and equilibrium of the nervous processes is preserved. It may break down at any step of the nervous hierarchy under the influence of any great stress or as the result of emotion, and it must be rare indeed for anyone not to experience a want of control at one time or another. It is only right to notice here that at any rate two examples occur of an exaggeration of the inhibitory process under the influence of emotion—viz., blanching of the face and a stoppage of the salivary secretion from fear. The conclusion, then, to be drawn from these remarks in regard to the lowest centres is that they are naturally well controlled in infancy and childhood, but are liable to disturbances of function, generally in the direction of loss of inhibition, as soon as the emotions are developed.

The next question that arises is, does inhibition proceed *pari passu* with the development of function? *A priori* considerations would lead to a negative answer, for it can be shown that some of the lower centres are controlled by others at a higher level, and reasons have been advanced for supposing that this is a general rule. If this be so it must follow that at the time of development every function is under deficient control, for this is a function of a higher level. Soltmann has indeed proved this to be so in regard to very young puppies, and many facts point to the same conclusion in man. The immediate result of the development of the salivary glands, as has been seen, is an overflow of saliva and it is only at a later period that they are presumably fully controlled. The same thing is strikingly illustrated in the case of the urinary centre, which is controlled by another in the medulla, so that section of the cord produces exactly the same incontinence of urine which exists in infants. This centre is evidently developed at a considerable period of time after the sphincters themselves are capable of normal function. I would regard the greater frequency of the pulse in childhood as another example of delayed inhibition, although it is many years before it is perfected. The function of the vagus is to act as a damper upon the heart's action, and it is therefore little in play when the pulsations are about 160 per minute in utero, but its activity increases in inverse proportion to the diminution in the frequency of the beats until they reach 70 or 72. The gradual decrease of respirations up to adult age is explicable on the same hypothesis. Another peculiarity of childhood is its liability to pyrexial outbursts—e.g., the tem-

perature often bounds up to 103° or 104° F, which apparently causes only slight inconvenience. A dose of *santonine* is given, an ascarrus is ejected, and the temperature falls. Now a heat centre almost certainly exists, and I take it that it is its development ahead of its checking apparatus which renders it liable to disturbance by means which are ineffectual in the adult. In regard to the muscular twitchings during an infant's sleep, it may be noticed that they occur in the fingers and more rarely in the toes, wrists and ankles. Exactly the same thing may be seen in a sleeping dog. The cause for this may possibly be found in the fact that the development of the brain of the infant is chiefly in the direction of the centres underlying these movements, which are at that time, therefore, feebly controlled. The occurrence of similar twitchings during sleep only is explicable on the supposition, as I have suggested elsewhere,² that inhibition is then less perfect than in the waking state. The frequency of laryngismus, tetany and convulsions during infancy is probably due to this evolution of function ahead of its checking apparatus. If this be so, it is manifest how all important is a due development of this function of inhibition. If it do not preserve a certain definite relationship with the evolution of the various functions of the body, a liability to convulsive disorders is engendered which may leave its impression upon the whole life history of the individual. Regarded from this point of view, precocity is not a desirable attribute, for it generally, if not always, happens in these children that development proceeds at such a rate that inhibition does not preserve its relative position in the process and lags behind. Thus the characteristic of precocity is instability. And so it is often with genius, of which precocity may be supposed to be the youthful equivalent, inhibition frequently fails to keep pace with the excessive development of function. It is inhibition—the power of control—which parents should seek to cultivate in their children far rather than development of function, for this is possible later in life, whereas control, once lost, may never be regained. In childhood every thing should be done to place the individual under the most favourable conditions of existence, it should, if possible, be suckled and have plenty of fresh air and exposure to sunlight. The absence of these tends to the development of rickets, which seems in a peculiar way to retard the development of inhibition, as witness the proneness to convulsive disorders of all descriptions. In a healthy child there should be no such predisposition, for although control is much less complete than in the adult the conditions of life are so much more simple, the demands upon it so much less violent, that under ordinary circumstances the amount of inhibitory power should be ample to ensure a perfectly even existence.

The highest centres of the brain are liable to grave disturbance at the onset of the exanthemata and other febrile disorders. In childhood the highest then developed centres are the motor, and hence convulsions often mark the commencement of fever, whereas at a later period it is initiated by delirium. *Apocryphos* of this, it may be noted that, in precocious children, delirium may accompany such a slight pyrexia as that which accompanies an ordinary tonsillitis. The occurrence of night terrors, too, coincides with the early stages of mental development, and at a later period, when a new phase of life is introduced by the development of emotions, hysteria, in all its protean aspects, assumes an important place in nosology. Many of the manifestations of this disorder are so clearly due to a want of controlling power that it seems only a fair induction to assume that all are of the same nature. It would appear, therefore, that the development of mental processes, equally with that of the motor, is signalled by a condition of instability similarly arising from a deficiency of inhibitory power. Chorea is another example of loss of control occurring at this age, it is peculiar in that there is a strong hysterical tendency, illustrating psychological deficiency of inhibition coexisting with manifest motor loss of control. So great is the mental defect in some cases of chorea that actual insanity has resulted, and I have recorded one case occurring in a child of seven years. Insanity, however, is extremely rare in children, not only because of the exuberance of energy, which ensures the stability of the then developed centres but on account of the limited sphere of their surroundings and their non-liability to be swayed by the different passions and emotions which agitate the nervous system of adults.

To sum up the nervous functions of the new born infant consist entirely of those subserving and regulating the purely vegetative processes of the body. These are for the most part situated in the spinal cord and the region of the medulla oblongata. The motor and the pre frontal areas of the brain are yet an unexplored region, a mass of protoplasm and neuroglia, which is soon to be channelled in all directions by communicating strands of extreme complexity. The younger the child the more nearly does it approach the type of a purely reflex organism, composed of a series of segments. For purposes of illustration the brain of an adult may be compared with the Imperial Government of our own country, which exercises absolute and undisputable control over every unit of population. It is made up of a Home Secretary, Minister for War, Chancellor of the Exchequer &c., and every question of Imperial moment is determined by it alone. Matters of purely local interest, on the other hand, are settled by the county councils, whose duties are modified or enlarged by the Central Government. In a similar manner the nervous centre of a reflex arc regulates the functions of that particular segment and is in a way autonomous. The nervous system of a new born infant may be regarded as constituted of a series of reflex arcs arranged along the spinal cord and medulla. These centres carry on the vegetative processes of life and represent muscles in their simplest combinations. Reflex action is thus the chief feature in the nervous processes at this period, and its manifestations are the more pronounced as the highest restraining centres are as yet undeveloped. Of this the cremasteric reflex is an admirable example. In the adult it is only obtained by tickling the skin over a somewhat restricted area on the inner side of the thigh, whilst in the infant it is easily evolved by tickling the skin on the lower third of the leg, and in some cases even the testicle on the opposite side is drawn up, though to a lesser extent. Thus not only is the reflex sensory area more extensive in the child, but the discharge of the centre upon excitation is at once more decided and widespread. It is not surprising to find reflex disturbances extremely common during the first few years of life. To express this in the words of the above simile, the arrangement of reflex arcs with their respective areas before and immediately after birth may be compared with government by county councils, which is amply sufficient to carry on the simple needs of the economy. With the increasing complexity however of the nervous processes, the enlarging environment and relationships of life, it becomes necessary to have a central government in order to regulate and control the lower centres and so carry on the various and diverse functions of adult life. From what has been said of the cremasteric reflex it would seem that the inhibition of reflex centres is exerted in three directions: the sensory area from which the motor act proceeds is diminished, the resulting contraction is lessened, and the range of action in the centres is limited. The consideration of the reflex centres (for what is true of the cremasteric probably applies also to the others though less easily demonstrable) leads to the conclusion, already arrived at, that the function of the centres is developed ahead of its appropriate checking apparatus. Of the centres already developed at birth I have shown that those associated with the superficial reflexes—the heart, the respiration, micturition and defecation—are inefficiently controlled compared with what obtains in the adult. In regard to the deep reflexes Eulenbergs asserts³ that the knee-jerks are well marked at birth but decrease gradually in the course of the following few weeks. In regard to the absence of controlling power by the brain, it is worthy of remark that the pyramidal tracts down which cerebral impulses proceed are in an undeveloped state during infancy, and are only evolved when the brain takes over the control of the spinal centres. Coincidentally with the evolution of the brain the centres already developed at birth become more and more “damped down” and are rendered more stable. As has been pointed out, however, certain of them become liable to disturbance when the emotions are developed and nearly always in the direction of loss of control. If it be true that the lowest centres of all are incompletely controlled at birth, and that, too, when they are in a forward state of development, how great must be the deficiency of inhibition in those higher centres which are developed at a much later period. The importance of the recognition of the fact that centres develop ahead of their appropriate inhibitory apparatus cannot be over estimated.

Not only does it explain the instability of the infant's brain, but it emphasises, perhaps more than anything else could, the folly of forcing the minds of the young. By so doing a most certain foundation is laid for the development of neuroses which may mar the whole subsequent life of the individual. The fact that girls are generally more precocious than boys would suggest that greater care is necessary in their training, for proportionally with their precocity there is an increased liability to chorea, hysteria and other nervous affections having their foundation in a defect of inhibition. The moral of this paper is to restrain a precocious child, do not cram a backward one, but with a judicious education of the mind let them indulge in healthy recreation and develop their motor centres before those of a much higher level.

Bournemouth.

VISCERAL TUBERCULOSIS IN LEPROSY.

By BEAVEN RAKE, M.D. LOND.,

MEDICAL SUPERINTENDENT OF THE TRINIDAD LEPROSY ASYLUM.

FOR some time past it has been well known to observers that tubercles generally diffused through the viscera and often breaking down into large cavities in the lungs are frequently found in necropsies on lepers. Caseous bronchial and mesenteric glands are also by no means uncommon. Speculation has naturally been aroused as to the nature of these tubercles, and various opinions have been expressed. I have already discussed the subject fully elsewhere,¹ and I propose here to describe a few recent experiments which seem to settle the question.

CASE 1.—A creole of mixed race aged twenty eight was admitted to the Trinidad Leper Asylum on Dec. 1st, 1875, with mixed leprosy of ten years' duration. After her admission the tubercles became absorbed and the disease remained stationary, the patient being in fair health. On Dec. 12th, 1891—sixteen years after admission—chest symptoms were noticed. These gradually increased and she died of phthisis on Aug. 10th, 1892. The necropsy next day showed the lungs to be full of tubercles. At the apices these were yellow, caseating and about the size of peas. Lower down, the tubercles were grey and milky. The spleen was lardaceous and the kidneys showed mixed tubal and interstitial change. The median nerves were slightly enlarged.

Experiment 1.—An incision was made over the nape of the neck of a guinea pig, and a piece of one of the pulmonary tubercles, about one eighth of a cubic inch in size, was inserted beneath the skin, the incision being closed with a silk suture. On Nov. 11th, 1892, there was an ulcer about half an inch long at the site of inoculation. It was covered with a yellow scab and there was much thickening round it. Behind each ear was a globular mass about half an inch in diameter. Further back behind the left ear was a small mass about the size of a pea. This was punctured and found full of caseous material. Some of the contents were stained with magenta, and under one twelfth a few bacilli were found which were indistinguishable from tubercle bacilli. In the left axilla was a similar mass and there was a nodule about the size of a small shot in the right axilla. On Nov. 23rd the nodule behind the left ear had burst and that further back had almost disappeared. On Dec. 4th the guinea pig was killed. There was still an unhealthy looking indolent ulcer at the site of inoculation covered with a loose scab. Behind the ears were caseous masses. The axillary glands were enlarged and one in the left axilla was suppurating. The lungs were full of translucent nodules about one eighth of an inch in diameter. In the spleen were several mottled dark red and yellow nodules about one-third of an inch by a quarter of an inch in size. The other viscera were normal. Fresh cover glass preparations from the nodules in the spleen and lungs showed, when stained with magenta, bacilli indistinguishable from those of tubercle. Tubes of glycerine-agar were inoculated from the nodules in the lungs and from the caseous axillary gland, but no culture of tubercle bacilli was obtained.

Experiment 2.—Another guinea pig was inoculated in exactly the same way from the same patient as the last. On Nov. 11th, 1892, there was a scab about a quarter of an inch

³ Charcot. Leçons sur les Maladies du Système Nerveux, tome II, 22.

¹ British Journal of Dermatology, February 1890, p. 53. Guy Hospital Reports, vol. XLVIII, 1891, p. 38.

long at the site of inoculation and much thickening round the incision. Behind each ear was a lump about the size of a pea. The axillary glands on both sides and one right inguinal gland were enlarged to the size of No 4 shot. On March 6th, 1893 the guinea pig died. At the site of inoculation was a circular ulcer about half an inch in diameter. Its edges were undermined, it was covered with a hard scab and there was thickening round. Behind the right ear was a lump about half an inch in diameter, which on incision was found to be full of thick caseous pus. A left inguinal gland was enlarged and caseating. The lungs were full of translucent nodules varying in shape and ranging in size from a small shot to No 3 or 4. There were similar masses in the liver, but here they were of a bright yellow colour. They were more numerous along the thin anterior edge and one nodule was breaking down into pus. The spleen, kidneys and intestines were healthy.

CASE 2—A negress aged seventeen was admitted to the Trinidad Leprosy Asylum on Nov 5th, 1887, with mixed leprosy of four years' duration. On admission she had suspicious looking circular ulcers and an irregular granulating surface on the left leg. Clostrisation progressed rapidly under iodide of potassium and perchloride of mercury. Soon after she was admitted she had an outbreak of leprosy tubercles on the face, accompanied by fever. This soon passed off and the tubercles on the face and hands ulcerated. During her stay in the asylum the patient suffered frequently from fever and pains in the limbs, also from iritis on two occasions. In April, 1892, a large sloughing ulcer formed over the right shin. After this chest symptoms became pronounced and she gradually sank. She died from hæmoptysis on Aug 30th. The necropsy next day showed old healed ulcers on the legs and distortion and loss of substance in the fingers and toes. Most of the tubercles had been absorbed. The median nerves were slightly thickened. The lungs were full of tubercles of various sizes, at the left apex was a ragged cavity about the size of a Tangerine orange and traversed by thickened vessels, it contained blood clot and evidence of recent hæmorrhage, at the back of the right lung was a smaller cavity. There were tubercles on the parietal pleura. The larynx was thickened and ulcerated and the vocal cords were almost destroyed. The spleen and kidneys contained several small yellow tubercles, and there were one or two in the liver. There were tubercles on the peritoneum.

Experiment 3—A guinea pig was inoculated beneath the nape of the neck with a piece of tuberculous lung from the above patient about one sixteenth of a cubic inch in size. On Nov 11th, 1892, there was an indolent ulcer at the site of inoculation about one inch long. There was much thickening round it. In each axilla were two enlarged glands varying in size from a No 6 shot to a pea. There was also an enlarged gland in each groin. The guinea pig died on Dec 10th, the ulcer at the site of inoculation was in exactly the same condition as a month ago, the cervical and axillary glands were enlarged, caseous and about half an inch in diameter, the lungs were full of small translucent nodules about one-eighth of an inch in diameter, there were small yellow nodules in the liver, the other viscera were healthy. Numerous bacilli, indistinguishable from tubercle bacilli, were found in the nodules of the liver and a few in the pulmonary deposits.

Experiment 4—Another guinea pig was similarly inoculated from the same patient. On Nov 11th, 1892 there was an indolent ulcer three quarters of an inch long at the site of inoculation. It was scabbed over and there was thickening around. In the left axilla was an enlarged gland about one inch by half an inch in size. In the right axilla was a gland about the size of a No 4 shot, and in the left groin was a gland the size of a pea. On Jan 1st, 1893 the guinea pig died. The ulcer at the site of inoculation was about the same. The lungs showed irregular translucent masses precisely similar to those in the other guinea pigs. The liver was full of bile stained deposits like those already described. There were pale, irregular masses in the spleen. The axillary glands on both sides and the left inguinal glands were enlarged and caseating. The kidneys and intestines were healthy. In these four guinea pigs inoculated from two different patients the lungs presented the same appearances. In each case there was an indolent, thickened ulcer at the site of inoculation, and caseating glands were common to all of them. The only variations observed were in the other viscera. In two cases only the liver showed nodules, in one case the spleen only,

and in one case both liver and spleen. Bacilli indistinguishable from those of tubercle were also found in several of the specimens examined. It is well known that attempts to inoculate guinea pigs with leprosy have always failed, and it therefore seems justifiable to conclude that all these guinea pigs suffered from tuberculosis set up by inoculation with tuberculous material from the lungs of lepers.

I asked Dr Slater to examine some of the specimens. This he has kindly done, and he tells me that he believes the lesions to be those of tuberculosis. He is going to show sections from the viscera and some of the original specimens at the Pathological Society.

It may, perhaps, be objected that these guinea pigs might have been suffering from tuberculosis before inoculation. This, I think, is to say the least, extremely unlikely, for I have examined the bodies of many guinea pigs after inoculation with leprosy material and have never before found tuberculosis.

There remains a much larger question, which I shall only allude to very briefly at present. Are leprosy and tuberculosis due to the same bacillus, modified perhaps in the case of the former by some difference of environment? This theory was advanced tentatively by Danielssen² some time ago, and certainly every year the difficulty in differentiating the two bacilli seems to increase. They respond to almost the same colour tests and the alleged difference in size cannot be relied on if, as Danielssen asserts, leprosy bacilli from Spain are larger than those from Norway. I have already³ called attention to the frequency with which in cases of tuberculated or mixed leprosy there is rapid absorption of cutaneous tubercles during the last few weeks of life. In these cases the necropsy shows the viscera to be full of milky and yellow tubercles. The following case, which terminated a few days ago is the most typical I have seen.

CASE 3—A negro aged eight was admitted to the Trinidad Leprosy Asylum on June 3rd, 1889, with mixed leprosy of eighteen months' duration. There were isolated tubercles on the face, legs and right arm. These were excised and cauterised with temporary success.⁴ Fresh crops of tubercles, however, soon appeared, and in a year's time he was worse than on admission. In December, 1890, the tubercles began to ulcerate. In December, 1892, there was a constant high temperature, and on Jan 17, 1893, it was noted that the tubercles were disappearing. Absorption went on rapidly the fever continuing, but there was hardly any cough. He died on March 1st, 1893. The necropsy showed much wasting of the body. Nearly all the cutaneous tubercles were absorbed. The median nerves were enlarged. Both lungs were filled with milky tubercles. The spleen was full of bright yellow tubercles, some of them as large as peas. There were numerous milky tubercles in the liver, and a few in the kidneys. The bronchial and mesenteric glands were caseous. Guinea pigs were inoculated with pieces of tubercle from the liver and spleen. This case seems to suggest that the visceral tubercles were the result of absorption of cutaneous tubercles during the last few weeks of life. It may, perhaps, be objected that the bronchial and mesenteric glands could hardly become caseous in that time, but I would point out that in the first guinea pig inoculated there was extensive caseation in three months. If then the absorption of cutaneous leprosy tubercles produces visceral nodules which, when inoculated in guinea pigs set up tuberculosis, there exists undoubted tuberculosis derived indirectly from leprosy. It is evident that the last word has not been said, and I hope that further experiments, which I am now making, will throw more light on the subject.

The present position may be stated as follows. 1. Inoculation experiments have shown that the visceral nodules in lepers are tuberculous and not leprosy. 2. It is quite possible that leprosy and tuberculosis may be caused by the same bacillus, but this has not yet been proved.

A PLEA FOR THE OPERATION OF PARACENTESIS ABDOMINIS IN THE TREATMENT OF ASCITES

By SURGEON MAJOR A. S. FAULKNER,

F.R.C.S. (Edin.),
INDIAN MEDICAL SERVICE.

THE presence of ascitic fluid exists in the majority of cases as a symptom of some form of chronic disease and is especially prevalent amongst the ill-nourished and emaciated. Very rarely, indeed, do we see it constituting an actual unexplained affection of the peritoneum. It is not my intention to refer to the etiology of ascites; its causes are numerous. My object is to draw attention to the incontestable fact that large numbers of these cases are treated as if the presence of the ascitic fluid constituted an actual disease, instead of being treated directly as a localised symptom of some recognised malady. I should like to add my experi-

ence in which I tapped the abdomen during 1831 when in India. The majority of the cases it will be seen were cases of splenic ascites, in extremely common symptom of a disease characterised by a hypertrophied spleen and which is essentially prevalent amongst those who are ill-nourished and have been subjected for years to malarial influences in a tropical climate. Of these cases one man was tapped four times, another three times and two others twice each, and on several the operation was only resorted to once. The remaining cases were of hepatic origin and in one instance a patient was tapped three times with satisfactory results. The indications for the removal of ascitic fluid are usually referable to the additional symptoms caused by the mechanical pressure of the fluid on the thoracic and abdominal viscera. The operation itself being so simple it is not worthy of a detailed description. There are, however, one or two important practical points to be noted in its performance. Of these the complete evacuation of the bladder immediately before the operation is, perhaps, the most important. It sometimes happens during an operation that the fluid suddenly ceases to flow through the cannula, the cause of this is that the internal aperture of the cannula gets blocked by the entrance of a portion of

* In each case all fluid was removed at one sitting.

ence of the treatment of ascites by the direct method of removing all the fluid at one sitting from the peritoneum, and to this I will confine my remarks without reference to the constitutional treatment of the several diseases of which it forms a symptom. Before submitting an epitome of cases I will state the reasons on which I based my decision to adopt this method of treatment. 1. Because ascites, no matter from what cause its presence may be excited, is a symptom of a grave and urgent nature and is usually developed in the more advanced stages of the disease with which it is complicated. 2. Because its presence causes pain and much unnecessary discomfort to the patient. 3. Because any other modes of treatment such as the administration of purgatives, diaphoretics, diuretics, absorbents &c. are utterly untrustworthy and greatly add to the exhausted and debilitated condition of the patient. 4. Because the operation of paracentesis abdominis is practically devoid of danger and it can be repeated several times on the same subject with advantage. 5. Because the result of the operation benefits the patient and improves his general condition and thereby tends to augment the chances of curing his actual constitutional disease by subsequent treatment.

The following tabular statement gives the details of cases

in which I tapped the abdomen during 1831 when in India. The majority of the cases it will be seen were cases of splenic ascites, in extremely common symptom of a disease characterised by a hypertrophied spleen and which is essentially prevalent amongst those who are ill-nourished and have been subjected for years to malarial influences in a tropical climate. Of these cases one man was tapped four times, another three times and two others twice each, and on several the operation was only resorted to once. The remaining cases were of hepatic origin and in one instance a patient was tapped three times with satisfactory results. The indications for the removal of ascitic fluid are usually referable to the additional symptoms caused by the mechanical pressure of the fluid on the thoracic and abdominal viscera. The operation itself being so simple it is not worthy of a detailed description. There are, however, one or two important practical points to be noted in its performance. Of these the complete evacuation of the bladder immediately before the operation is, perhaps, the most important. It sometimes happens during an operation that the fluid suddenly ceases to flow through the cannula, the cause of this is that the internal aperture of the cannula gets blocked by the entrance of a portion of

the omentum. In such cases a blunt pointed probe ought to be introduced through the cannula and the protruding omentum pushed gently inside at the same time by a slight movement the cannula should be directed in a slightly oblique line so as to obviate a recurrence of the accident. If ascites is complicated with general anasarca (affecting usually the lower extremities and the scrotal sac) it is my routine method of treatment to extend the principle of direct removal of fluid to these regions by making innumerable surface punctures all over the lower extremities and scrotum. This simple procedure combined with the elevation of the feet, a suspensory bandage to the scrotum and complete rest in bed in the recumbent position gives most satisfactory results and in a very short time the patient is in a better condition for the performance of the major operation.

I have been induced to offer the above observations by a perusal of Dr W. B. Cheesle's remarks on the treatment of ascites,* and as a result of my own experience I am able to endorse his opinions and advocate early paracentesis abdominis in the treatment of ascites.

long at the site of inoculation and much thickening round the incision. Behind each ear was a lump about the size of a pea. The axillary glands on both sides and one right inguinal gland were enlarged to the size of No. 4 shot. On March 6th, 1893 the guinea pig died. At the site of inoculation was a circular ulcer about half an inch in diameter. Its edges were undermined, it was covered with a hard scab and there was thickening round. Behind the right ear was a lump about half an inch in diameter, which on incision was found to be full of thick caseous pus. A left inguinal gland was enlarged and caseating. The lungs were full of translucent nodules varying in shape and ranging in size from a small shot to No. 3 or 4. There were similar masses in the liver, but here they were of a bright yellow colour. They were more numerous along the thin anterior edge and one nodule was breaking down into pus. The spleen, kidneys and intestines were healthy.

CASE 2.—A negress aged seventeen was admitted to the Trinidad Lepor Asylum on Nov. 5th, 1887, with mixed leprosy of four years' duration. On admission she had suspicious looking circular ulcers and an irregular granulating surface on the left leg. Clostrisation progressed rapidly under iodide of potassium and perchloride of mercury. Soon after she was admitted she had an outbreak of leprosy tubercles on the face, accompanied by fever. This soon passed off and the tubercles on the face and hands ulcerated. During her stay in the asylum the patient suffered frequently from fever and pains in the limbs, also from irritis on two occasions. In April, 1892, a large sloughing ulcer formed over the right shin. After this chest symptoms became pronounced and she gradually sank. She died from hæmoptysis on Aug. 30th. The necropsy next day showed old healed ulcers on the legs and distortion and loss of substance in the fingers and toes. Most of the tubercles had been absorbed. The median nerves were slightly thickened. The lungs were full of tubercles of various sizes, at the left apex was a ragged cavity about the size of a Tanager's orange and traversed by thickened vessels, it contained blood clot and evidence of recent hæmorrhage, at the back of the right lung was a smaller cavity. There were tubercles on the parietal pleura. The larynx was thickened and ulcerated and the vocal cords were almost destroyed. The spleen and kidneys contained several small yellow tubercles, and there were one or two in the liver. There were tubercles on the peritoneum.

Experiment 3.—A guinea pig was inoculated beneath the nape of the neck with a piece of tuberculous lung from the above patient about one sixteenth of a cubic inch in size. On Nov. 11th, 1892, there was an indolent ulcer at the site of inoculation about one inch long. There was much thickening round it. In each axilla were two enlarged glands varying in size from a No. 6 shot to a pea. There was also an enlarged gland in each groin. The guinea pig died on Dec. 10th, the ulcer at the site of inoculation was in exactly the same condition as a month ago, the cervical and axillary glands were enlarged, caseous and about half an inch in diameter, the lungs were full of small translucent nodules about one eighth of an inch in diameter, there were small yellow nodules in the liver, the other viscera were healthy. Numerous bacilli, indistinguishable from tubercle bacilli, were found in the nodules of the liver and a few in the pulmonary deposits.

Experiment 4.—Another guinea pig was similarly inoculated from the same patient. On Nov. 11th, 1892 there was an indolent ulcer three quarters of an inch long at the site of inoculation. It was scabbed over and there was thickening around. In the left axilla was an enlarged gland about one inch by half an inch in size. In the right axilla was a gland about the size of a No. 4 shot, and in the left groin was a gland the size of a pea. On Jan. 1st, 1893, the guinea pig died. The ulcer at the site of inoculation was about the same. The lungs showed irregular translucent masses precisely similar to those in the other guinea pigs. The liver was full of bile stained deposits like those already described. There were pale, irregular masses in the spleen. The axillary glands on both sides and the left inguinal glands were enlarged and caseating. The kidneys and intestines were healthy. In these four guinea pigs inoculated from two different patients the lungs presented the same appearances. In each case there was an indolent, thickened ulcer at the site of inoculation, and caseating glands were common to all of them. The only variations observed were in the other viscera. In two cases only the liver showed nodules, in one case the spleen only,

and in one case both liver and spleen. Bacilli indistinguishable from those of tubercle were also found in several of the specimens examined. It is well known that attempts to inoculate guinea pigs with leprosy have always failed, and it therefore seems justifiable to conclude that all these guinea pigs suffered from tuberculosis set up by inoculation with tuberculous material from the lungs of lepers.

I asked Dr. Slater to examine some of the specimens. This he has kindly done, and he tells me that he believes the lesions to be those of tuberculosis. He is going to show sections from the viscera and some of the original specimens at the Pathological Society.

It may, perhaps, be objected that these guinea pigs might have been suffering from tuberculosis before inoculation. This, I think, is to say the least, extremely unlikely, for I have examined the bodies of many guinea pigs after inoculation with leprosy material and have never before found tuberculosis.

There remains a much larger question, which I shall only allude to very briefly at present. Are leprosy and tuberculosis due to the same bacillus, modified perhaps in the case of the former by some difference of environment? This theory was advanced tentatively by Daniëlsen² some time ago, and certainly every year the difficulty in differentiating the two bacilli seems to increase. They respond to almost the same colour tests and the alleged difference in size cannot be relied on if, as Daniëlsen asserts, leprosy bacilli from Spain are larger than those from Norway. I have already³ called attention to the frequency with which in cases of tuberculated or mixed leprosy there is rapid absorption of cutaneous tubercles during the last few weeks of life. In these cases the necropsy shows the viscera to be full of milky and yellow tubercles. The following case, which terminated a few days ago, is the most typical I have seen.

the omentum. In such cases a blunt pointed probe ought to be introduced through the cannula and the protruding omentum pushed gently inside, at the same time, by a slight movement the cannula should be directed in a slightly oblique line, so as to obviate a recurrence or the accident.

If ascites is complicated with general anasarca (affecting usually the lower extremities and the scrotal sac) it is my routine method of treatment to extend the principle of direct removal of fluid to these regions by making innumerable surface-pricks all over the lower extremities and scrotum. This simple procedure combined with the elevation of the feet a suspensory bandage to the scrotum and complete rest in bed in the recumbent position, gives most satisfactory results and in a very short time the patient is in a better condition for the performance of the major operation.

I have been induced to offer the above observations by a perusal of Dr W B Cheale's remarks on the treatment of ascites,¹ and as a result of my own experience I am able to endorse his opinions and advocate early paracentesis abdominis in the treatment of ascites.

THE USE OF CATGUT LIGATURES IN OVARIOTOMY

By SURGEON MAJOR D CHAS DAVIDSON, I M S,
CIVIL SURGEON, SATARA, INDIA.

It has generally been held that catgut ligatures are unsuitable in cases of ovariectomy, owing to the danger which may arise from their becoming loosened or absorbed too quickly, but the following case would appear to show that they can be employed with safety. The benefits to be derived from the use of such ligatures in preference to silk, apart from the supposed danger, are sufficiently manifest. The now almost universal procedure of cutting the pedicle short, ligaturing and carefully replacing it in the abdominal cavity, renders the application of the least irritating ligatures compatible with safety desirable, and nothing of this nature that has as yet been introduced into surgical practice has been found to be so little liable to set up inflammation or to so readily undergo absorption as catgut. There is also an advantage in employing it for deep and superficial sutures, especially the former, to the abdominal incision, as it becomes absorbed and there is no occasion to remove the sutures. Indeed the first dressings placed over the wound do not under such circumstances require to be disturbed at all until firm union has taken place, thus saving the patient pain and worry, both liable to set up inflammatory symptoms, and avoiding any danger of interfering with the healing process.

A married Maratha woman, aged about twenty five, suffering from ovarian tumour, was on June 3rd, 1892, placed on the operating table, and the usual precautions were taken and arrangements made. Surgeon Major Hill, A.M.S., of the Satara Station Hospital, kindly assisted me. An incision about three inches long was made in the median line midway between the umbilicus and pubes, the deeper layers of fascia and the peritoneum being divided on a director. On passing the hand into the abdomen slight adhesions were found, but not of an extensive nature. The tumour, which was of considerable size and multilocular, was emptied as far as practicable by means of Spencer Wells' "ovariotomy trocar," but part of the contents, being of a semi solid nature, would not pass through and had to be removed with the tumour. The few adhesions were gently separated and the tumour was turned out of the abdominal cavity. The pedicle, which was fairly long, was twice transfixed with a needle armed with catgut ligatures which were carefully tied, ligaturing the pedicle in halves. A third ligature of the same material was then thrown round the whole thickness and firmly secured, after which the pedicle was divided and the ligatured portion gently replaced within the abdominal cavity, which was carefully sponged out. The edges of the incision were accurately brought together by means of deep and superficial catgut sutures and a dressing of iodoform and boracic wool was applied. In the evening, about seven hours after the operation, her condition was as follows: there was no sickness, the temperature was 100.6° F, the pulse was 120, small and soft, and she was almost free from pain.

June 4th, morning.—Temperature 99°, pulse 102. She is almost free from pain in the wound, but complains of pain in the head. She passes urine freely, but the bowels have not been opened. She takes milk well. In the evening the temperature went up to 100.8°.

5th.—Temperature in the morning, 99° F, in the evening, 101.2° F. She slept well, but complains of a little pain, chiefly in the right thigh, the tongue is clean, but the bowels have not been opened.

6th.—She is going on well. Morning temperature, 99°, evening temperature, 101.4°.

7th.—She has had no sleep and complains of pain. Temperature 100.

8th.—The bowels have been moved and she slept well. Temperature 100. She complains of pain in the wound.

9th.—Temperature normal. She complains of some pain in the right thigh and in the wound. The bowels have been moved.

10th.—Temperature normal. She slept well. The bowels have acted.

11th.—Temperature normal. She complains of pain and has slight diarrhoea.

12th.—There is severe pain in the wound. She had no sleep till midnight. The bowels acted twice. The temperature is normal.

14th.—Evening temperature 102.1, pulse 122. The bowels were moved once. She has nausea and retching.

16th.—Temperature slightly below normal.

17th.—She is free from pain and tenderness. The stools are natural.

From this date she progressed favourably without any bad symptom up to July 2nd, when she was discharged cured, free from any feeling of uneasiness and with the incision firmly united. No sutures were removed from the wound, the catgut having become absorbed, and the dressings were rarely disturbed during the healing process.

ANTISEPTIC MIDWIFERY

By CLEMENT GODSON, M.D. ABERD., M.R.C.P. LOND. &C.,
CONSULTING PHYSICIAN TO THE CITY OF LONDON LYING IN HOSPITAL.

At the annual meeting of the Governors of the City of London Lying in Hospital, held in February, it was reported that no death had occurred amongst the women delivered in the hospital during the past year. The last death took place in May, 1891, so that there has been no mortality amongst the mothers for nearly two years, and not only so, but I am able to state, since I am called in consultation to every case of serious illness, that there has not been one arising from septic causes amongst the 907 women delivered during this period. I do not call attention to this in a boasting, but in a very thankful spirit, for this hospital has not always been able to report so favourably. In 1870, when I first became connected with the institution, the mortality during the year was 4 per cent. In the ten years from Jan 1st, 1873, to Dec. 31st, 1883—the hospital being closed in 1878—the mortality was over 2 per cent. (1 in 46). In the four years from January, 1880, to January, 1884, it was over 3 per cent. (1 in 32). But during the last six years, that is from January, 1887, to January, 1893, the death rate has been 1 in 319, or 0.31 per cent. This is a remarkable reduction, and naturally one looks for the reason. I have no doubt it results chiefly from the very thorough manner in which the matron sees that the antiseptic management of labour is carried out. Every patient has a vaginal douche of a solution of perchloride of mercury (1 in 2000) administered during labour, and another after the delivery of the placenta, and six more of these douches are given subsequently, generally one night and morning. After this, Condy's fluid or carbolic acid lotions are used. But it is not so much by the use of these douches that immunity from septicæmia is ensured as by the scrupulous attention that is paid to the hands and the finger nails of all those coming into contact with the patients. It is seen that the nails are kept short, that the nail brush is never neglected, and that after washing the hands in soap and water they are plunged in the sublimate lotion.

In a lecture which I gave in 1887 at the Midwives' Institute on "Antiseptic Midwifery" I spoke of the risk, according to published statements, of mercurial poisoning from the employment of sublimate lotion, and I said that in the fifteen months that it had been universally employed at the City of London Lying in Hospital not a single instance of it had occurred. I am now able to state that, during six more years of its employment there, no symptom of poisoning by it has been observed, which proves, I think, that all fear of such may be dismissed. Of course it cannot be expected that this absence of mortality amongst the patients can continue for long, for it must be borne in mind that deaths from all causes are included. I, for one, firmly believe in the occurrence of puerperal peritonitis from traumatic causes, injuries during labour, and rupture of a pyosalpinx, for instance, for I have seen such in private practice where the antiseptic management has been most rigidly carried out. But what it is desired to secure, and I believe has been arrived at, is the prevention of puerperal infection being communicated from one patient to another in the lying in hospitals. Surely this is the time to do honour to Semmelweis, who was the first to point out the causes which gave rise to puerperal fever in lying in institutions and the means of preventing its occurrence by the use of disinfectants. Dr Theodore Duka, in a pamphlet published last year, states that in May, 1847, Semmelweis issued orders that, in the clinique under his control in the General Hospital, Vienna, every person, before proceeding to examine any patient,

should thoroughly wash his hands with liquid chlorine or chlorinated lime-water, and in a work he published at a later date, entitled "Die Aetologie &c.," he insisted on "removal of maternity wards from insanitary surroundings—scrupulous attention to general cleanliness and frequent use of antiseptics in every form." Semmelweis died in 1865 at the age of forty-seven, and certainly until recently his name has been forgotten—if ever known—by most of us. It is now, however, proposed to erect an international monument¹ to his memory in his native town of Budapest, in recognition of his discoveries in connexion with the etiology and prevention of puerperal fever, and, for the purpose of obtaining contributions from the United Kingdom, India and the British Colonies, an executive committee has been formed of which Sir Spencer Wells is chairman and Dr. Cullingworth honorary treasurer. The maximum subscription has been fixed at one guinea in order that the project may meet with general support. I venture to hope that this communication may stimulate some of my professional brethren to contribute.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL AND THERAPEUTICAL

EXCISION OF THE PECTUM AND PART OF THE SIGMOID FLEXURE (TWELVE INCHES) FOR MALIGNANT DISEASE.

By F. A. PURCELL, M.Ch., M.D. R.U.I.,
SURGEON TO THE CANCER HOSPITAL, BROMPTON

A WOMAN aged forty-six was admitted into Marsden Ward of the Cancer Hospital on Feb. 23rd, 1893. She is the mother of seven children, the youngest being five years old. She is a thin spare woman of nervous temperament and highly excitable. She menstruates regularly, the bowels are troublesome, being generally relaxed, never constipated. She suffers from pain in the body after straining. For some months she has been passing blood with her motions. About five weeks before she presented herself here she consulted Dr. Robinson of Yaxley. He made an examination and found a growth per rectum, and recommended her to seek further advice at the Cancer Hospital. On examination the sphincter was found to be dilatable, easily admitting two fingers, the folds of the intestine fell down. On insinuating the finger further up to its utmost, and on pressing the perineum, a hard mass was reached, the bowel and mass were freely movable and by gently drawing the parts downwards the finger passed through the diseased tube and was able to be got beyond the growth. The entire circumference was implicated and disease was more pronounced anteriorly and to the left where ulceration had occurred. The lumen of the tube was patent, no obstruction proceeding to occlusion existing. Nothing could be made out on examining per vaginam.

On Feb. 23th she was placed on the table, having been previously prepared by having copious enemata administered and the bladder emptied. She was anaesthetised with ether by Dr. English and placed in the lithotomy position, the legs being supported by Clover's crutch. On examining the rectum a quantity of solid and liquid faeces escaped, and the bowel had to be washed out to cleanse it, I was assisted by my colleagues, Messrs. Jesse, Cotterell and Barber. My colleagues made an examination and concurred in the attempt to remove the disease by total extirpation, although it was situated beyond the usual limit very considerably. The sphincter ani was stretched but left intact, the mucous membrane, one inch inside, was incised all round, as also were the muscular and serous coats thus freeing the bowel about one inch from the margin of the anus. The rectum was now detached from its surrounding—the posterior wall of the vagina was dissected off and stopped by means of the finger nail and scissors, any bleeding vessel was seized with clamp forceps. At about four

and a half to five inches up, the peritoneum anteriorly was opened, which gave exit to a flow of coloured fluid. Some further attachments of the recto-sigmoid mesocolon were divided, as also other bands—a procedure which released the bowel, the part with the growth had to be gradually brought down and was delivered between the fingers. The white longitudinal bands indicating the sigmoid flexure were observed descending over the growth and spreading out upon and being lost over the upper part of the rectum. Two inches above the growth was the spot selected where the bowel seemed well clear of the disease, and there the gut was cut across with scissors, the end was clamped with five pairs of torsion forceps, the parts were well douched and cleansed, and all the vessels ligatured, the upper end was then drawn carefully down without any tension and sutured with interrupted silkworm gut sutures to the mucous membrane at the anus. Some of the free mucous membrane, as being superfluous was cut away, a rubber drainage-tube was lodged behind the bowel, a pad of absorbent wool was secured by a T bandage, and a morphia suppository administered. She passed that night fairly well. The next day her temperature rose, but fell the second day after, when she passed a large motion, and up to the present she is doing well.

The measurements of the piece of bowel were taken when it was removed, the gut was afterwards placed in spirit and water and has shrunk considerably and requires stretching to obtain the same measurement as when it was fresh. The piece removed measured twelve inches and as one inch of mucous membrane was left above and inside the anus the gut was cut thirteen inches from its margin. From the anal extremity of the specimen to the lower limit of the disease was a distance of seven inches, the disease occupies three inches, and two inches of sound bowel shows above. The white longitudinal bands descending from the sigmoid flexure are seen running over the growth and passing down for two inches below the lower border of the disease. The bowel posteriorly, being the middle and lower portion of the rectum, is devoid of peritoneum and is shredded where it had been peeled away from the sacrum, also anteriorly where it had been detached from the posterior wall of the vagina. The line of the reflexion of the peritoneum is seen lower down in front than in its posterior aspect, the three inches occupied by the disease has much thickened the gut all round, being more pronounced in the front and to the left side, where it has broken down the finger having burst through the ulceration during manipulation at the time of operation. On laying open the bowel the lumen of the tube is patent. The mucous coat is infiltrated and ulcerated, the ulceration being more extensive where the disease was most pronounced, the muscular coat is also infiltrated. The disease is cylindrical epithelioma.

Ulceration ending in perforation would have evidently preceded occlusion, as the lumen of the tube is patent. This would have ended either by perforating into the abdominal cavity or adhesive inflammation might have prevented this for a time by agglutinating the diseased and ulcerated portion of the bowel to some neighbouring part possibly to some coil of the small intestine or to the uterus and vagina.

Manchester-square, W.

A CASE OF ACUTE ALCOHOLIC POISONING

By WM. BERRY, F.R.C.S. IREL.

HOV. MEDICAL OFFICER, ROYAL ALBERT EDWARD INFIRMARY, WIGAN

CASES of acute alcoholic poisoning are of sufficient rarity to cause the following case to be worthy of record in THE LANCET.

A man aged thirty-three, at the time of the occurrence following the occupation of a labourer in a railway goods yard, on Feb. 11th, at 2 P.M. partook with his comrades of some whisky drawn out of some casks supposed to have been empty. He is said to have drunk between ten and fifteen ounces of the spirit. At 2.20 P.M. he was seen by a carter to go and sit on a form in the machine office in a state of drunkenness. Within a few minutes he fell to the ground in a deep sleep. This carter left him at 3 P.M., thinking that he was merely drunk and would sleep off the effects of the liquor and then go home. At 6 P.M. the carter found him in the same condition, and on the man's wife arriving to seek her husband the latter was lifted on to a form. Mr. Berry was sent for and saw

¹ A special meeting of the medical profession in aid of the movement to erect an international monument to Semmelweis was held in the Library of the Royal College of Physicians on Oct. 24th 1892, a report of which appeared in THE LANCET of Oct. 29th.—ED. L.

him about 7 P.M. He found him lying on the form with his face somewhat flushed, the pupils contracted almost to pin points, the conjunctivæ insensitve and suffused, respiration slow but regular and somewhat laboured, and the radial pulse slow and scarcely perceptible. As nothing could be done on the spot a hypodermic injection of twenty minims of ether was given, and the man was removed in an ambulance to his own house, which was not very far off. On arriving there he was placed on a couch and was found in the same state of profound coma, it being impossible to rouse him. A faint spirituous odour could be detected in the breath, and so without loss of time the stomach pump was used and the stomach washed out with warm water. The water returned almost clear, only containing a little mucus, and had no odour of spirits. (It may be mentioned here that he had not taken any dinner that day and had eaten nothing since breakfast.) The patient was then undressed and put to bed, and another hypodermic injection of ether was given. The extremities were now extremely cold, the conjunctivæ still insensible, the pupils minutely contracted, respiration was laboured; but not stertorous, the pulse was weak and the heart sounds were very indistinct. Attempts to rouse the patient were of no avail. Hot bottles were applied to the extremities and the sides, and mustard plasters over the præcordial region, the nape of the neck and the calves of the legs. The hands and arms were vigorously rubbed, and the patient was covered with warm blankets. Another hypodermic injection of ether was given before the patient was left. On a second visit at twelve, midnight, reaction was found to have commenced the body and extremities were warm and vesication had taken place at the left hip where one of the hot bottles had been applied. But the pupils were still contracted, the conjunctivæ insensitve, coma was quite as deep, the pulse slightly improved, and the heart sounds were still very indistinct. A hypodermic injection of atropine ($\frac{1}{4}$ gr.) was given and some hot coffee ordered for the patient as soon as he showed signs of being able to swallow. Cloths dipped in vinegar and water were also ordered to be applied over the forehead and temples. He never recovered consciousness and died at 9 A.M.

Necropsy (thirty hours after death), by Mr FOREMAN, L.R.C.P., L.R.C.S. Edin.—The body was well nourished. There were some marks of psoriasis guttata on the left thigh and forearm. There were no marks of violence, but there was slight emphysema over the right first and second ribs at the seat of the hypodermic injection. Rigor mortis was complete. There was hypostatic congestion on the dorsum. On removing the calvaria the skull was found to be somewhat thin, the dura mater was slightly adherent and very much congested, the vessels being filled with dark fluid blood. There was no effusion of serum on the surface of the brain. On removing the brain there was no effusion at the base and the vessels were normal. On cutting into the substance of the brain it appeared healthy. There was no effusion in any of the ventricles. On opening the thorax the lungs were found to be healthy, there were slight adhesions of the left pleura, and there was very little dark fluid in the pleural cavities. The pericardium contained very little fluid. The heart was in a state of diastole, the right ventricle was empty and the valves were healthy. The left ventricle contained a small quantity of dark fluid blood, but the valves were healthy, though the lining membrane and muscular wall were of a dark chocolate colour. The stomach distended with gas, contained a little greenish mucus. The mucous membrane had very dark patches scattered over it, but there was no corrugation. No smell of alcohol could be detected. The liver was congested. The gall bladder was half filled with bile. The spleen was normal. The intestines were healthy. The kidneys were slightly congested, the capsula was not adherent. The bladder was healthy and contained about six ounces of urine.

Remarks by Mr BERRY—This case is interesting from the suddenness of the onset, the perfect insensibility, the persistent minute contraction of both pupils (as it is usually stated that in cases of alcoholic poisoning the pupils are dilated), the slowness of the pulse and the snoring respiration in contradistinction to the stertorous breathing of coma from compression, the absence of the clammy skin seen in opium poisoning, and the reaction which took place without any restoration to consciousness, together with the failure of treatment to avert a fatal issue. I have to thank Mr Das for the notes of the case.

ST SAVIOUR'S UNION INFIRMARY, EAST DULWICH GROVE

ULCERATIVE ENDOCARDITIS OF MALARIAL TYPE IN A
MAN WHO HAD FORMERLY HAD AGUE.

(Under the care of Dr C GROSS, late Medical Superintendent,
reported by THEODORE FISHER, M.D. Lond.)

THE malarial type of ulcerative endocarditis does not appear to be a common variety of the disease. Amongst the fifty three cases recorded by Dr F Taylor in the Guy's Hospital Reports for 1891 there is no example, and Dr Osler at the time of his Gulstonian Lectures had not seen a case. The latter, however, refers to cases recorded by other observers—e.g., Drs Wilks, Bristowe, Coupland, Lancereux, Leyden and Ormerod—and mentions that some have noted the previous occurrence of ague. Dr Lancereux briefly refers to a case in a young man aged twenty five, who had contracted intermittent fever during residence in Africa, and was treated in 1860 in the Hôpital de la Pitié for a cardiac affection accompanied by a paroxysmal fever, against which sulphate of quinine remained powerless. The patient died, and his heart showed lesions of ulcerative endocarditis.¹ The same writer quotes another case in a man aged twenty five, who seven years before had suffered from fever in Africa. About 1 P.M. in the day he had rigors followed by heat and abundant sweating. The paroxysms although not occurring with great regularity, continued for the last three weeks of life.² Dr Ormerod, in the Gulstonian Lectures for 1851, quoted a case that was under the care of Dr Bond of Cambridge, in which, although no history is mentioned, the district from which the report comes is worthy of note. A gentleman aged sixty one, suffering from heart disease, which was found afterwards to be of the ulcerative form, "had two paroxysms (rigors) recurring pretty regularly every day—viz., at 4 A.M. and 4 P.M."³ Another interesting case is recorded by Dr Bristowe. About four months previously to admission the patient thought she caught ague whilst staying at a village in Hampshire. She was attacked by rigors with a cold, hot and sweating stage soon after her return to London. When first seen by Dr Bristowe, seventeen days before death, rigors occurred with remarkable regularity at intervals of about twelve hours the temperature intermitting between 95° to 97° and 104° to 105°. After the first four days the temperature was sometimes irregular, sometimes of the malarial type. It is possible that in this case rigors ushering in the fatal disease were mistaken for ague.⁴ Quite recently, Dr Osler has recorded two cases of chronic intermittent fever associated with malignant endocarditis,⁵ one of which was under his own care. In this case, occurring in a man aged forty-three, there was "an undefined history" twenty years before of what the patient called "chronic malaria." The malarial type of ulcerative endocarditis doubtless does occur without a previous history of ague, as is shown by the interesting temperature chart of one of Dr Coupland's cases,⁶ yet it is not unreasonable to suppose that when this disease has followed malaria the previous attacks of fever have had some effect upon the character of the temperature. The attacks may be supposed to have left their stamp upon the heat centres, so that when those centres were upset there was a tendency to act upon certain lines. The altered blood of the majority of febrile diseases finds it difficult to overcome the daily habit of the nervous system, but those habits having been outgrown and new paths at least for a time, laid down when fresh but somewhat similar disturbance occurs, it is not difficult for the nervous organisation to act upon those same paths and to run to similar extremes. The following case is interesting from that point of view. Periods

of temperature of malarial type were more or less complicated with those of a pyæmic character, but that is only what one might be led to expect. Fresh bursts of septic infection from time to time dominate the daily *role* but as the heat mechanism recovers from the shocks it elects to act in some accustomed manner.

A well built muscular, but rather anæmic man aged thirty-three was admitted to the infirmary on Jan. 8th, 1891. The history taken by Dr Kent states "In the army five years and eight months, invalided for heart disease. Was in the Zulu campaign and in Ceylon, had fever and ague (quotidian and tertian) also slight dysentery." There was no history of rheumatism. Recently the patient's mother was written to and asked if he suffered from recurrence of the malaria since his return to England. She answered that she saw little of him, but that "he had shivering attacks at times after he came home." The description of the condition of the heart is as follows: "Apex fifth space nipple line, impulse heaving regular, no thrill, to-and-fro bruit at right base, systolic rough and conducted to right clavicle, diastolic less harsh and heard down the sternum and in the left vertebral groove. At the apex is a soft low pitched bruit

hands were sometimes cold at the onset, but a cold stage was not well marked. The rigors however were severe and sometimes lasted all the time that the temperature was rising. He several times vomited as the rigor was passing off. Marked sweating as the temperature fell was only occasional, but the skin was generally clammy. Quinine, antipyrin and antifebrin were all powerless to restrain the rise. From Feb 7th to 13th the temperature again became irregular, but on the 14th reverted to the malarial type, this time, however, there was a rise on one day followed by two on the next, thus answering to the type that has been called 'semi tertian.' This lasted, as is seen from the chart, for eight days, then double rises occurred on two consecutive days. For the last three days of life some of the evening temperatures were not recorded, but the character of extreme intermission remained the same. The rigors became more and more severe, the patient calling out and groaning as they commenced. Death took place during one of them and whilst the temperature was rising. At the necropsy the heart was found to weigh twenty six ounces, large masses of friable granular vegetations were found on all the aortic valves, which were thickened and contracted. Perfora-

Abridged two hour chart, the highest and lowest temperatures being selected. It may be described as semi-tertian, a single rise on one day being followed by two on the next. The single rise is the most constant in time being highest once at 5 P.M. and then on three alternate days at 3 P.M. The second of the double rises at first postpone two hours on three alternate nights then reaches its maximum at the same hour for some other night. The first of the double rises is generally highest at 5 A.M. or 7 A.M. For the last three days of life, unfortunately some of the evening temperatures were not recorded.

* The hours at which the various temperatures were recorded.

conducted into the axilla. Pulse collapsing regular. The abdomen was full, but there was no dulness in the flanks and no œdema of the legs, the liver was three inches below the ribs but repeated examination failed to detect the spleen. To anticipate matters it may be mentioned that surprise was great on finding at the necropsy a large somewhat flattened-out soft spleen weighing twenty-one ounces. Dr Tooth has recently recorded a case in THE LANCET in which a large spleen in ulcerative endocarditis was overlooked. To return to the clinical history for the first fortnight the morning and evening temperature chart showed on two or three days intermissions between 97.6 to 98.4 and 102.4 to 103.6, on other days the temperature in the morning did not descend below normal. Taken every two hours the temperature for the third week, although remitting about five degrees daily was more pyæmic than malarial. On Jan. 31st, however it adopted a regular rise and fall from subnormal to 104 or 104.6, the rise being associated with a rigor. The onset occurred from three to five o'clock in the afternoon and reached its maximum regularly for eight days with one exception, at 11 P.M., and by 11 A.M. the following morning the temperature was generally subnormal. The

tion of the coats of the aorta had taken place above the right posterior valve, union of the sheath of the vessel with the wall of the right auricle having prevented rupture and extravasation of blood. The aperture admitted the tip of the little finger. Behind the same valve a sinus led into a small abscess cavity in the inter ventricular septum. From half to three-quarters of an inch below the valve this abscess cavity communicated with the left ventricle by an aperture sufficiently large to admit a grooved director. It was surrounded by a large mass of vegetations. A few of the chordæ tendinæ of the mitral valves were ruptured. The spleen was large (weighed twenty one ounces), soft, and almost diffident. The kidneys as is not uncommon in this disease were large, pale and fatty. They weighed twenty-three ounces.

Remarks by Dr T. FISHER.—Dr Lancereaux has recorded eight cases of ulcerative endocarditis with a history of malaria or with suspicion of that disease, and appears to think that there is some connexion between the two. Another French writer, Dr Duroziez, considers that malaria is capable of pro-

ducing simple endocarditis and has collected twenty cases of ordinary cardiac disease in patients who have had ague, but with no history of rheumatism. It is difficult to believe that in the above case malaria eleven or twelve years previously can have had anything to do with the fatal character of the heart lesions, but since there was no history of rheumatism I suppose Dr Duroziez would claim the case in support of his view. That the patient was invalid for cardiac disease soon after having suffered from malaria is certainly singular. One cannot, however, lay stress upon a negative history of rheumatism.

Medical Societies.

MEDICAL SOCIETY OF LONDON

Aphasia due to a Fall on the Head—Croupous Pneumonia in Children.

An ordinary meeting of this Society was held on March 27th, Dr De Havilland Hall, Vice president, in the chair. Dr C E BEEVOR gave the details of a case of Aphasia due to a Fall on the Head. The patient was a carpenter aged fifty, who fell from a scaffold fourteen feet on to the left side of his head. He was unconscious for fifteen minutes, but soon afterwards he walked home, where he complained of pain in the head and kept repeating the sentence, "Had a fall." The next day he was drowsy and could not answer questions. There was no definite paralysis. Four days later he came under observation, when the following symptoms were noticed as regarded his speech. He could speak voluntarily, but imperfectly, and talked a good deal of nonsense, he could understand spoken commands and write spontaneously, but could not understand written commands, or repeat spoken words, or pick out objects named to him, or write from dictation, or copy printed characters in writing, and could not name objects shown to him, though he could recognise their use. The patient recovered in about three weeks. The nature of the lesion was probably meningeal hæmorrhage or simple concussion and was situated probably over the visual word centre in the supra marginal and angular gyri.—Dr DE HAVILLAND HALL asked whether the sense of smell had been tested. If anosmia were present and were unilateral it would probably not be discovered by the patient.—Mr SPENCER WATSON asked whether there were any abnormal subjective sensations of smell and remarked that optic neuritis sometimes supervened in these cases. He inquired to what Dr Beevor attributed the recovery.—Dr WALTER CARR commented on Dr Beevor's remarks on the inability of the right hemisphere to discharge the functions of the left in cases of aphasia, and asked if an exception might not happen in the case of very young children.—Dr BEEVOR, in reply, said that owing to the difficulty the patient had in expressing himself it was impossible to be sure about absence of smell, he never complained of any perversion of that sense. There was no change in the optic discs. The recovery, he believed, followed on absorption of effused blood. He did not think that even in children the right hemisphere was capable of assuming the functions of the damaged left side.

Dr FRANCIS HAWKINS read a paper on Croupous Pneumonia in Children. The communication was based on the investigation of 220 cases, and the conclusions at which he arrived were fully illustrated by diagrams. He showed that most cases occurred during March, May and July, the fewest in January, August and December. They occurred as a rule independently of antecedent disease, and in the great majority the onset could not be attributed to any definite cause. Fifty of the cases occurred under the age of five years, 120 between five and ten, and fifty between ten and fourteen. The disease was most frequent at the ages of five and nine respectively. Connecting his table with a further series of over 700 cases occurring mostly in adults, compiled by Drs Hadden, Mackenzie and Ord, he found that the frequency of the affection gradually rose from the fifth to the twentieth year. Its onset was usually sudden and the most prominent symptoms of invasion were vomiting, cough and pain, whilst rigors and convulsions were very infrequent and hæmoptysis was extremely rare. An arrangement of symptoms into groups showed that the nervous system was the one most frequently affected. The average daily temperature before crisis was 103° to 104° F, and in about one seventh of the cases the fever assumed the hectic type, though

in only three was this found to be associated with the presence of pus. The sixth was the commonest day of crisis, it being very frequent also on the seventh and eighth days, in basic pneumonia it was rather later than in apical. He regarded the coarser signs of the disease, such as dulness, tubular breathing &c, as of value more for estimating the gravity of the case than for the mere recognition of the disease, a dull tympanic note was often present before any marked variations in the breath sounds were discernible. Out of 146 cases the base of the lung was attacked in 69, the apex in 45, and in the remainder the primary seat of the disease was at other points. The most rapid respiration noticed was 68, typical rusty expectoration was present in seven cases, the youngest being aged six. Pleurisy coexisted in sixteen cases, pus being removed from the chest in three. Pulmonary gangrene occurred once. An endocardial bruit originated during the course of the disease in six cases and pericarditis in one. Albuminuria supervened in seven cases and herpes in thirty six, the latter affection being in one case on the arms. Delirium was rather more frequently associated with apical than with basic pneumonia. As to treatment he thought that ice if used in a left-sided pneumonia might so slow the heart as to give rise to dangerous symptoms. With regard to alcohol, discretion was required in selecting those cases in which its exhibition was needed and those from which it should be withheld.—Dr DE HAVILLAND HALL asked Dr Hawkins whether he had any figures showing the relative frequency of croupous and catarrhal pneumonia, in many of the croupous cases there was cerebral complication.—Dr ALEXANDER MORISON thought that in some cases he had seen pneumonia develop as a metastasis. To control the heart, it was of equal efficacy to apply the ice to the forehead as to the chest. He considered that the administration of alcohol required great care, as it blunted the reflex sensibility of the nerve centres. The action of digitalis in this malady was less unfavourable in children than it was in adults.—Dr PASTEUR spoke of the difficulty in discriminating some of the less marked cases from lobular pneumonia.—Dr BRADWOOD asked if there were any distinctive clinical symptoms which would aid the separation of the catarrhal cases. The onset, he thought, was usually gradual. Cough was not a valuable symptom, as children repressed it, and the temperature was not of much help. Assiduous poulticing was better than ice as a measure of treatment, and alcohol was of value chiefly as a sedative.—Dr W CARR remarked on the variations in type seen in children and on the very rapid fall of temperature which often accompanied the crisis. As the prognosis was so good, only expectant treatment was needed.—Dr HAWKINS briefly replied.

CLINICAL SOCIETY OF LONDON

Pseudo bulbar Paralysis—Epithelioma of Lip—Modified Progoroff's Operation—Patent Meckel's Diverticulum—Fracture of Skull—Exceptional cases of Peripheral Neuritis—Treatment of Shock by Transfusion.

A CLINICAL meeting of this Society was held on March 24th, the President, Sir Dyce Duckworth, in the chair.

Dr NEWTON PITT showed a case of Pseudo bulbar Paralysis in a man, it was probably of cerebral origin.

Mr BARKER showed an exceptional case of Epithelioma of the Lip. The disease, starting at the angle, had spread along both the upper and lower lips and there were no signs of similar growth commencing at the opposite angle. The man had been the subject of syphilis and was very much addicted to chewing tobacco. There were some patches of leucoplakia on the tongue. Its malignant nature was proved microscopically.

Mr BARKER likewise brought a man on whose foot he had operated according to Le Fort's Modification of Progoroff's Method. The advantage was the early date at which the patient was able to bear his weight upon the stump, it being only seven weeks since the operation.

Mr BATTLE exhibited a female infant with a Polypoid Extrusion at the Umbilicus. At its apex was a minute orifice from which escaped a small quantity of faecal matter. The protruded portion proved to be the mucous membrane of Meckel's diverticulum. The bowels acted normally, showing that the gut below the diverticulum was properly developed. The existence of this condition in the female had been

doubted. He had seen a case somewhat similar in a child a few days old in which there were two openings

Mr WALLIS showed a boy who had made a good recovery from an extremely severe Compound Comminuted Fracture of the Skull.

Dr HALE WHITE read a paper on Two Exceptional Cases of Peripheral Neuritis—the one septicæmic, the other due to lead. The first case was that of a man aged thirty three, who came into the hospital suffering from mitral regurgitation, great œdema of the lower extremities and an unhealthy ulcer on the left leg. The skin all round it was red and inflamed. Two days afterwards the ulcer had doubled its size, it was very foul, and the patient had a high temperature. He complained that he could not bend his hands, and it was found that he had a wrist-drop on both sides. During the next few days the weakness of the extensors increased so much that three days afterwards power of flexion and extension of the hand, wrist and elbow on both sides was lost, supination was very weak and pronation was completely paralyzed. The movements of the shoulders were weak. The supinator longus on both sides was paralyzed. There was no loss of sensation, but the muscles and the musculo-spinal nerves were extremely tender. Two days after this date, as the ulceration was rapidly spreading the leg was amputated at the knee, the symptoms of neuritis were worse. The second case was one of saturnine neuritis. A man aged forty five, who had lead colic twice, and who worked in white lead works, was suddenly taken ill with very acute pains in his limbs and body, especially in the lumbar region. On admission he was found to be suffering from intense abdominal pain as also severe pain and degeneration in some of the muscles. The periphery of each field of vision was considerably constricted. On the right side the arch of the soft palate was much lower than on the left. The right posterior pillar of the fauces projected inwards more than the left. Both pillars approached the uvula when the patient said 'Ah,' but the right did not return so far outwards as the left. The uvula was not deflected. Taste was impaired. Food did not return through the nose. It appeared as though the elevator palati was paralyzed. This became well first, but the posterior pillar for some time remained nearer the middle line than its fellow, probably from weakness of the opponents to the palato-pharyngeus. The left wrist was slightly swollen. The muscles of the limbs and the accessible nerves were all extremely tender to pressure. He had marked double-wrist drop. The flexors were weak. Inspiration was normal. The lower extremities were in all movements almost completely paralyzed. The pupils were equal. There was early optic neuritis. The bowels were confined and there was vomiting. The knee-jerks and plantar reflexes were lively. He remained under observation six weeks and was discharged well. During his stay in the hospital the following additional symptoms were observed, painful swelling of various joints with subsequent grating in some of them, numbness coldness paræsthesia and loss of temperature sense in various parts of the body, the muscle sense in the hands was also impaired. The PRESIDENT remarked that though some of the cases of neuritis from toxic causes were associated with arthritis the joint affection in some of them might be due to gout. He regarded the swellings on the backs of the hands as trophic nature.—Dr HADDER pointed out the absence of evidence that the joint affections were due to trophic changes. In cases of osteo-arthritis and of chronic rheumatic arthritis it had not been proved that they were dependent upon diseases of the peripheral nerves, though he would not go so far as to say that peripheral neuritis never caused joint disease. There were many other poisons besides lead which would cause hyperæsthesia. In both alcoholic neuritis and diphtheritic paralysis there had been often noticed an exaggeration of reflexes previously to their abolition.—Dr HALE WHITE, in reply said that he had only met with this one instance of septicæmic neuritis, but a collection of such cases had recently been published. He insisted on the clinical fact that these different poisons produced different types of neuritis. The diphtheritic cases were quite different from those due to alcohol, the hyperæsthesia in the former being sometimes very severe. He quoted an instance in a syphilitic patient which ended in complete recovery.

Mr MAYO ROSSON read a paper on the Treatment of Shock by Transfusion or Infusion. He described two cases in detail and mentioned others in which he had found that the infusion of several pints of normal saline solution into the circulation ward off impending death in cases of intense shock after operation. The cases specially described were one

of enucleation of a large fibro-myoma of the uterus and another of amputation at the hip-joint in a young adult, for sarcoma of the upper part of the thigh. In neither case had there been any material loss of blood, but death was apparently imminent from shock. Both patients were saved by the means adopted. After quoting from several authorities to show the similarity in the symptoms of syncope and collapse, Mr ROBSON pointed out that it had been clearly shown that shock was naturally due to paralysis of the heart and vaso-motor paralysis of the abdominal vessels, the sudden dilatation of which might simulate sudden hæmorrhage. He remarked that in cases of shock without serious hæmorrhage the blood was driven into the large abdominal veins, where for the time being it was useless, leaving the head and extremities in a state of anæmia. Now, if by injecting several pints of blood fluid into the vessels one could force the blood into circulation again, the effect should be at once manifest by a filling of the vessels in the head and extremities, and although the blood would be diluted the increased quantity (three to four pints) would be sufficient to fill the dilated and partially paralyzed abdominal vessels as well as the vessels supplying the parts essential to life, the heart, moreover would be likely to be stimulated by the blood being driven into it. The case he related seemed to bear out these suggestions. The subject was one which should be capable of experimental proof, and if his suggestions were to be considered to be worthy of further prosecution he had no doubt that proof could be furnished in that way. His own conviction from personal experience was so distinct that it had become his practice, whenever he went to perform a capital operation, to include amongst his instruments a transfusion apparatus and a packet of salt sufficient to make four pints of normal saline solution.—Dr LEONARD REMFEE referred to a case of ovariectomy which was performed at the Great Northern Hospital, in which three hours after the operation the patient began to become faint, and when he saw her she seemed to be on the point of death. Forty five minutes after the injection of a pint and a half of saline solution she had greatly improved, and she ultimately recovered, although for twenty four hours her pulse remained at 180 per minute. In another similar case in which the collapse came on at about the same time, but was more rapid, the patient died before transfusion could be performed. The necropsy proved that the collapse was due to shock, for the ligatures were secure and there was no hæmorrhage.—Mr PARKER said that the cases in which one would expect the least benefit from this treatment were those in which no blood had been lost during the operation. In one instance in an infant he had adopted the continental method of injecting a considerable quantity of saline solution subcutaneously, but the patient was in so collapsed a condition that the fluid was not absorbed. The Obstetrical Society had approved of the practice of injecting saline solution into the peritoneal cavity.—Mr BENHAM remarked that in cholera, in which these injections had been practised on the recommendation of Sir George Johnson, the results had been disappointing, the amelioration being immediate, but only temporary. Where the shock was not dependent on loss of blood, he suggested that resection would give the same relief with less trouble.—Mr F. BURGHARD had carried out this practice in a number of cases, but in only two was there no loss of blood. In one of these, after excision for hip-joint disease, two pints having been injected without perceptible effect, it was continued to four pints when the patient appeared much relieved, but three quarters of an hour later the pulse flickered and the patient died. In a second case, also there was some passing benefit, followed by a fatal result. These instances seemed to show that the proceeding was only of temporary benefit in cases of pure shock. If as was probable, the condition was due to accumulation of blood in the visceral veins it followed that the injection would only add to this accumulation. In one case, in which the operation was for fixing a movable spleen, the injection of a pint and a half of solution produced such intense dyspnoea that they were compelled to desist. In some thirty cases of shock from hæmorrhage he had seen the method practised with the greatest benefit.—Mr LEONARD BIRWELL said that in one case he had injected five pints into the femoral vein by means of a Higginson's syringe with good results though the patient died some days later from peritonitis.—Mr BATTLE referred to a case of intense shock in a man with rupture of the intestines, and four pints were injected after a long operation, with the result that the

patient rallied, though he died a few days later owing to the giving way of a stitch. In another case of ruptured spleen, the patient being very prostrate and the abdomen filled with blood, the injection of five pints of fluid so improved the condition of the patient that he was able to operate. After the operation further collapse was met by the injection of another four pints, and the next day the patient declared that he felt as if there was nothing the matter with him.—Dr SOLOMON SMITH inquired at what pressure the injection was made. The collapse followed from the non passage of blood from the engorged right heart and not from failure of the systemic circulation.—Mr MAIO ROBSON, in reply, said that the right heart was not engorged in these cases, the blood being probably lodged in the relaxed vessels of the intestines, which were paralysed by the shock. He used a simple Higginson's syringe with a glass cannula. It was necessary to watch the patient for some time and repeat the injection if there were signs of fresh collapse, which had happened in several cases. Arguments based upon the conditions in cholera did not apply to these cases, and he failed to see how venesection could be of use. In several cases of operation for ruptured ectopic gestation he had infused into the peritoneal cavity, and a mere irrigation with normal saline solution resulted in a manifest improvement, but these cases were different, inasmuch as the collapse was due to loss of blood.

OTHER METROPOLITAN MEDICAL SOCIETIES

EPIDEMIOLOGICAL SOCIETY—At the meeting on March 15th (Dr J F Payne, President, in the chair) African Hæmoglobinuric Fever was the subject of a paper by Dr PATRICK MANSON, in which he deprecated the practice of explicitly or implicitly ascribing to malarial influences every febrile condition and internal lesion occurring in persons who had suffered from paludal fevers or who had resided for any length of time in the tropics. Some few, as yellow fever, dengue and beri beri, had been recently separated, but the differentiation of tropical fevers, probably more numerous than those of temperate climates, must be carried much further. Whatever the specific cause of malaric bacillus, plasmodium &c., the phenomena of periodicity, splenic enlargement and pigmentation were certainly not characteristic of hæmoglobinuric fever. The disease, though the most frequent and fatal of African fevers, and well described by several French and English observers, was ignored by systematic writers. The general course was that of sudden invasion, with rigors, vomiting and diarrhoea, dark, almost black, scanty urine and "jaundiced" skin. The temperature rose to from 104° to 108°. Next day the symptoms abated, the urine cleared, and on the third day the patient, but for the colour of the skin, might be convalescent. The essential phenomenon was the destruction of the blood cells, in the vessels the red corpuscles were seen to be of all sizes and forms, broken, discoloured and partly dissolved. The colour of the urine, to which the disease owed its popular name of "black water fever," was caused by the presence of broken down blood cells, epithelium casts and a quantity of granular debris and reddish brown pigment which slowly subsided or was carried down on boiling by the coagulum of albumen, leaving the supernatant fluid clear. The "jaundice" was not due to bile but to staining with altered blood pigment. Death supervened either (1) directly from exhaustion, or (2) from anaemia, or (3) from suppression of urine, followed by uræmic coma or convulsions. Previous attacks of malaria predisposed to it, but it was distinguished by the absence of any constant relation between the pyrexia and the danger, by the abrupt termination and by the uselessness of quinine, and it was possible that alleged previous malarial attacks were often cases of this disease of a milder type. It was apparently never heard of before 1850 and, though it seemed to be extending its area, was practically confined to tropical Africa (especially the west coast) and America. In the Congo, Senegal, Gaboon &c. nearly every European was attacked sooner or later, but mostly after the first year, the mortality varied from ten to fifty, averaging 15 per cent. It was frequent in Cuba, Martinique, Venezuela and other regions of tropical America, but there was no accurate or authentic record of a single case in or amongst persons returning from any part of Asia, nor even amongst the French in Cochinchina and Tonkin. He connected its extension to America rather than to Asia with greater commercial intercourse in that direction, and he

believed that the development of East African trade or the opening of the Panama Canal might lead to a wider distribution of this and other tropical diseases.—Dr BATTERSBY, speaking from a considerable experience of North and West Africa, agreed as to the non malarial nature of hæmoglobinuric fever, but maintained that all African fevers differed from the corresponding types of Asia in absence of periodicity &c. He had had seven consecutive monthly attacks of common malarial fever during his first residence in Africa, and subsequently four of hæmoglobinuric fever either there or on his return to England, with mean intervals of three months. One of the attacks being apparently excited by a chill. He doubted whether it differed essentially from other African fevers except in the hæmoglobinuria, which could not be deemed a specific feature.—Dr K McLEOD and Mr LAWSON having referred to the fevers of India, Dr COPMAN stated that though he had never been in the tropics, he had worked with Dr Bristowe at hæmoglobinuria, which he considered to be, whether here or in Africa, the direct effect of chills on persons in whom an excessive susceptibility was natural or acquired. None of their patients, adults or children, had ever been out of England, but their symptoms were essentially the same as those described by Dr Manson—namely, sudden fever ushered in with rigors, the temperature rising perhaps to 107°, vomiting, lumbar pain and faintness, and the urine within half an hour red, brown or black—though there was in none of them any renal disease. The attacks, which lasted about six hours, could always be induced experimentally by exposure with their free consent to cold air or water. No treatment beyond warm blankets &c. was found necessary. The children of Great Ormond street were all subjects of congenital syphilis and in them the attacks occurred whenever the day was cold and wet. None of the adults at St Thomas's Hospital had had syphilis, and but one, an omnibus driver, had ague, and was liable when at work to almost daily attacks, his spleen only being enlarged. The very best methods of microscopic examination failed to reveal any micro organisms. He might add that paroxysmal hæmoglobinuria was not unfrequent amongst horses, especially in Scotland, where it was sometimes fatal. It appeared from the paper and discussion that quinine was the only drug that had been tried, though Dr Manson himself had no confidence in it. He would suggest arsenic, which had proved of undoubted service in pernicious anaemia, and experiment showed it to restrain hæmolysis and to increase the hæmoglobin.—After some remarks by the PRESIDENT, Dr MANSON replied.

HARVEIAN SOCIETY OF LONDON—A meeting of this Society was held on Thursday, March 2nd, Mr Malcolm Morris, President, in the chair.—Mr ROUGHTON showed the Excised Bones of an Elbow joint, in which osseous ankylosis had taken place without the previous occurrence of suppuration.—Mr J JACKSON CLARKE showed the Brain and Spinal Cord of a boy who died of chronic hydrocephalus.—Dr WM HUNTER read a paper on the Diagnosis and Treatment of Pernicious Anaemia. The object of his communication was to direct attention to the points he considered of salient importance in making the diagnosis of this form of anaemia. He was accustomed to rest his diagnosis almost mainly on a consideration of certain changes found in the blood and in the urine and on certain associated changes in the liver and disturbances of liver function. Unlike other forms of anaemia, most of which were the result of impaired formation of blood, pernicious anaemia was due to an excessive destruction of the red elements and the plasma of the blood intermittent in character, occurring within the portal circulation and occasioned by substances foreign to the healthy body introduced into the blood by absorption from the gastro intestinal tract. The chief clinical features associated with this destruction were—1. As regarded the blood, a percentage of hæmoglobin either absolutely or relatively higher than that of the red corpuscles so that, e.g., with a percentage of corpuscles of thirty or forty, one found the same or an even higher percentage of hæmoglobin. The explanation of this difference was that in pernicious anaemia there was no deficiency of iron in the body as was the case in these other forms, on the contrary, there was a large storage of it in certain organs, notably in the liver, and not infrequently also in the spleen, the bone-marrow and the renal cells. By this feature alone pernicious anaemia could be distinguished after death from those forms of anaemia which it most closely resembled during life. Another character of the blood he had found in a case he had recently examined, which he thought might ultimately prove to be of diagnostic importance, was a greatly re-

duced alkalinity of the blood. It was reduced by nearly one half whereas in a case of severe anaemia under Sir Hugh Beavor closely resembling pernicious anaemia, the alkalinity of the blood was normal. 2. As regarded the urine, the difference between the two kinds of anaemia was manifested by the darker colour of the urine of pernicious anaemia. The dark, saffron yellow colour of the former due to the presence of pigment derivatives of hæmoglobin, including "normal urobilin" and occasionally also "pathological urobilin," contrasted very greatly with the pale watery secretion of simple anaemia. 3. As regarded the liver, he was accustomed to attach considerable importance to the periodic occurrence of a slight degree of jaundice. Regarding the disease, as he did, as an infective one localised to the gastro-intestinal area, he thought the first indication was to treat that tract, and he recommended to this end the use of antiseptics, the best for this purpose, in his opinion, being beta naphthol and salol. The tendency to temporary recovery, so marked a feature of this form to anaemia, justified the hope that ultimately the disease would be found more permanently amenable to treatment.—Dr BRISTOWE related a fatal case of pernicious anaemia in which the urine remained to the end of a red brown colour. The patient was not jaundiced in the slightest degree and the urine contained no biliary colouring matter. He believed with Dr Hunter that under the term "pernicious anaemia" were probably comprised several diseases characterised by anaemia, but due to different causes and which, though often resembling one another in many important features were yet fundamentally distinct.—Dr PYE SMITH remarked that the title of this remarkable disease bestowed by Biermer in 1858 was inappropriate, for it was not *progressive* but intermittent in course and though undoubtedly grave it was not *pernicious* or malignant since temporary recovery was not infrequent and permanent cure had been several times recorded. It was a rare disease. It differed from chlorosis and from all secondary anaemia in the great diminution of blood discs, the hæmorrhages in the retina and elsewhere, the pyrexia and the fatty degeneration which ensued and in these respects it formed a natural group with Hodgkin's disease and leukaemia. Like them, it was not benefited by iron, but was almost always relieved by arsenic, as Dr Bramwell at first ascertained. Dr Hunter's important and interesting researches had not only extended those of Quicke on the accumulation of iron in the viscera, but had added much to our knowledge in other respects, particularly as to the reaction of the blood, a point of great interest, since this disease was probably of chemical rather than histological origin.—Dr HALE WHITE remarked that, on the whole, the evidence he had accumulated bore out Dr Hunter's contention, for out of twenty-nine cases of pernicious anaemia he found 41 per cent. gave a history of vomiting and 34.5 per cent. one of diarrhoea before admission. After admission 55 per cent. suffered from vomiting and 41 per cent. from diarrhoea, but at the post-mortem examination it was nearly always found that the gastric intestinal tract was healthy, when any changes were discovered they were slight and unimportant. The vomiting and diarrhoea were certainly not due to the arsenic, they were rather to be regarded as important symptoms of pernicious anaemia.—Sir HUGH BEAVOR remarked that all previous speakers had referred to the existence of other cases of essential anaemia, in which the prognosis was bad but yet which could not be included in the class described by Dr Hunter. He had no doubt the class of case Dr Hunter had done so much to elucidate was the commoner by far. He then related two cases.—Dr HUNTER replied.

HUNTERIAN SOCIETY—At the meeting of the Society on the 22nd ult., Mr F Gordon Brown, President, being in the chair Dr G NEWTON PITT read a paper upon the use of Venesection in the Treatment of Symptoms arising from Thoracic Aneurysm. He detailed the symptoms, paroxysmal cough, pain, dyspnoea, dysphagia and coma, and explained their causes. He read the notes of nine cases of thoracic aneurysm, with or without aortic incompetence, in which venesection, more or less frequently repeated, had been followed by relief to symptoms. In one case the patient was profoundly comatose, and on three occasions was restored to consciousness immediately by venesection. Dr Pitt thought venesection an efficient remedy for acute symptoms and would advise its use only with this object and not with a view to promote consolidation of the aneurysm by clot. He would treat thoracic aneurysmal cases by rest, recumbent

position, by iodide of potassium in gradually increasing doses, and with as limited an amount of fluid as is comfortable to the patient.—Dr F J SMITH thought frequent venesection dangerous to the patient and that no effect was produced until a dangerous stage was reached.—Dr PITT replied.—Dr HUMPHREYS read the notes of two cases of Recovery after Cheyne Stokes respiration. Both cases were females who had been suffering from broncho pneumonia following epidemic influenza. In one of the cases there was a history of mental shock followed by acute delirium and Cheyne-Stokes respiration lasting seven weeks. He thought stimulants of no use in these cases and advised sedatives. He suggested that the phenomena were due to the irregular stimulation of the two halves of respiratory centre. He had noticed that at first only the upper part of the chest wall seemed to move on inspiration but as the respiratory movements quickened they gradually involved the whole thoracic wall. Paraldehyde was the only drug which was of service.—Dr FOX and Dr GRANT each mentioned one case and Mr JOHN ADAMS mentioned two cases of recovery after Cheyne-Stokes respiration.—Dr F C TURNER read the notes of a case of Acute Strangulation of the Ileum by an Omphalomesenteric Band successfully treated by operation.—Mr F G BROWN related a case of sudden Acute Obstruction, where after seventy two hours of vomiting laparotomy was performed. The patient died on the eleventh day. At the necropsy acute kinking of the descending colon was found to have been caused by bands.—Dr HINGSTON FOX mentioned a case where he had successfully performed Abdominal Massage for Obstruction.—Dr TURNER, in reply, said that these cases were usually very acute, and no time ought to be lost before resorting to operation.

SOCIETY OF MEDICAL OFFICERS OF HEALTH—At the meeting on March 22nd, Mr Shirley F Murphy, President, in the chair, Dr NIVEN, having laid before the Society a memorandum issued by the North western Branch on the Prevention of Phthisis referred to the now almost universal recognition of the communicability of tuberculosis, complicated as the question was with those of its long incubation, heredity and intercurrent forms of disease. The idea was first grasped by the Italian physicians a century ago, but it was about thirty years since Villemin formulated it as clearly as was possible before the rise of bacteriology. He was followed by a number of experimenters in every country. Amongst the points established by Dr R. Koch was that, though capable of growing only in the presence of moisture and within certain limits of temperature, the bacillus tuberculosis produced in the body highly resistant spores, which retained their vitality and virulence unimpaired in dried sputa for 140 days or longer, and that it was by the pulverisation and aerial diffusion of these that they gained access to the respiratory passages. Koch proved by pure cultures the identity and inter-communicability of human, bovine and indeed, of all mammalian tuberculosis, but the non identity, original or acquired, of that of birds, the two requiring for their development the different temperatures of the mammalian and avian bloods. Dr G Cornet had done more than any man in the practical application of this knowledge, and his works were models of scientific research. He had shown that the great source of infection was in the dust deposited on ledges of walls furniture &c. Bacilli could generally be grown from the dust of rooms occupied by the phthisical unless great care were given to the disposal of sputa, but elsewhere and in the streets only negative results were obtained. Between the ages of twenty and thirty half the deaths of women were from tuberculosis, the milk of tuberculous cows contained the bacilli even when the udders were not diseased. Doubtless milk was the cause of much tuberculosis amongst children, though there were a few cases on record of truly congenital disease. Calves, however, were seldom affected. Local lesions and pulmonary catarrhs pre disposed to tubercle, and the influence of damp was indisputable. He wished that the memorandum, amended in some details should be distributed amongst medical men, and phthisical patients would thus learn the danger of infecting others and of precluding their own recovery by constant self infection. He advocated the establishment of isolation hospitals in healthy open country sites, as a boon to the suffering poor and a means of checking the extension of the disease. He would have it made notifiable, with precautions as at Oldham, against multiple notifications, and showed by statistical tables that the cost would not be any difficulty. Tuberculosis in cattle should be brought under the Contagious Diseases (Animals) Act and county veterinary

inspectors should be appointed with the control of dairy farms and power to order the slaughter, with reasonable compensation, of obviously diseased animals.—Mr PAGET testified to the good effected in several Lancashire towns by voluntary notifications and disinfection.—Dr HERON said that in the western islands of Scotland there had long been a firmly-rooted belief in the communicability of phthisis and the most rigid isolation of the sufferers. He thought that if infection &c were avoided any so-called hereditary tendency might be disregarded.—Drs WILLOUGHBY and SYKES and Mr ARMSTRONG having taken part in the discussion, Dr NIVEN replied.—Mr ARMSTRONG then moved a resolution on the sale of tuberculous meat, which elicited considerable discussion, and which, at the suggestion of the President, was passed as a provisional expression of opinion only, pending the report of the Royal Commission. Dr SYKES considered any such resolution premature until by the substitution of public for private slaughter houses the examination of meat should be practicable at least in large towns.—Mr ARMSTRONG maintained, on the other hand, that the ends of inspection must be defined before the practice was undertaken. In Newcastle they had already notifications of bovine tuberculosis.—Dr HERON wished it to be known that the Society did not consider tuberculosis to be merely a local affection, though so long as the lesions were strictly localised the entire carcass need not be condemned. With this reservation the resolution was carried unanimously.

ROYAL ACADEMY OF MEDICINE IN IRELAND

SECTION OF PATHOLOGY

Fracture of Neck of Femur—Adenoma of Stomach.—Tuberculous Disease of Urinary Organs—Tuberculous Peritonitis—Ulcer of Stomach

A MEETING of this Section was held on Feb 17th, Mr F. A. NIXON, in the chair.

Professor E. H. BENNETT exhibited three specimens of Extra capsular Fracture of the Neck of the Thigh bone, in which the ordinary method of impaction was reversed the lower fragment being driven into the upper, and in which also the great trochanter was unbroken. He discussed the recorded cases of this variety of fracture and the recorded exceptions to the typical extra capsular fracture, referring particularly to the necessity of admitting forces other than falls or blows on the hip as causes of this form of injury.—Dr MYLES said he had examined a large number of specimens, and he thought these so called extra capsular fractures might be classified into those beside the head of the bone and those in the neighbourhood of the greater trochanter.—Professor BENNETT stated that intra and extra capsular fractures of the neck were each of definite type and were respectively inside and outside the capsular ligament.

Mr CONOLLY NORMAN made a communication on the subject of Adenoma of the Stomach, and exhibited a specimen showing this condition. The patient had been an idiot, thirty four years old. He was capable of complaining, but made no complaint of pain, and presented no symptoms referable to the stomach. There was no vomiting. His last illness was characterised by rapid wasting, without fever. There were sometimes mild attacks of diarrhoea, and there was rapidly increasing debility. At the necropsy the thoracic viscera were found to be normal. The liver was somewhat engorged, otherwise the abdominal viscera were normal, save the stomach. There were no enlarged glands. The mucous membrane of the stomach was everywhere thickened, and presented all varieties of polyposis, from large dendroid projections to small sessile wart-like growths. There was no ulceration and no tumour which could have been felt ante mortem. Microscopically the dendroid growths were found to consist of tubes and cysts lined with glandular epithelium. Between these tubes and cysts there was a good deal of muscular tissue, which seemed to be derived from the muscularis mucosae. Mr Norman pointed out that this case differed from the cases described by Brissaud in the youth of the patient, and from Menetrier and Rouillier's cases by the variety in form which the polypi presented.—Mr F. A. NIXON remarked that very frequently, in patients of weak intellect, subjective or objective symptoms are very badly marked. He remembered a case of melancholia in which the patient had a most extensive pleural effusion, and yet he

made no complaint nor had he any dyspnoea.—Mr NORMAN in replying, said he had met quite a number of patients of this class who died of phthisis and yet had no cough.

Dr H. T. BEWLEY showed the Urinary Organs from a man aged twenty four who had suffered from hip-joint disease since he was nine years old, the sinuses not closing till he was twenty one. He then began to suffer from frequency of micturition, which grew worse, the urine being mixed with blood and pus. Some eighteen months afterwards, being one day unable to relieve himself, he suddenly felt something give way, and the desire to micturate ceased. After some hours he passed a large quantity of urine per rectum. After this he passed nearly all his urine in this way. He gradually got weak and died in December, 1892. At the necropsy both kidneys were enlarged, the right consisting of a number of cavities with their walls, some of which contained thick green pus and others dry putty-like material, the left being enlarged and showing ulceration commencing at the papilla. Scrapings of these ulcers showed many tubercle bacilli. The ureters were thickened, but everywhere pervious. The bladder was small, its walls thin but inelastic, and its mucous membrane had disappeared. There were deep ulcers in the prostatic urethra at each side of the veru montanum, from which a sinus, admitting a No 12 catheter, passed backwards and opened into the rectum about two inches and a half above the anus. Through this sinus the urine had passed into the rectum. The rectum was otherwise normal. Both lungs showed traces of old tubercular mischief in their apices. Dr Bewley called attention to the rarity of such sinuses opening from the prostate into the rectum. It seemed, too, that in this case the sphincter retaining the urine in the bladder had been the muscles of the membranous urethra, as the prostatic urethra must have been full of urine at the time the sinus opened into the rectum. The mucous membrane of the rectum was perfectly normal, except for two very shallow ulcerations. Might it not be possible for a surgeon to open the bladder into the rectum with more comfort to a patient in cases of irritable bladder than into the perineum?

Mr CONOLLY NORMAN described a case of Tuberculous Peritonitis simulating Malignant Tumour. The patient—a male—was a person of unsound mind, who, under the influence of delusions, would not permit proper examination until almost the end. He had no cough. He wasted, became sallow, and finally slightly jaundiced. When he at last permitted examination nothing was detected amiss with his lungs, he was slightly ascitic, and a large tumour lay like a bar across the abdomen about the level of the umbilicus. This mass was movable. The diagnosis of cancer of omentum was arrived at, probably colloid, and secondary to cancer of the stomach. At the necropsy, however, it was found that there was no cancerous growth in the stomach or intestines. All the mesenteric tissues were thickened by dense infiltration. The great omentum [exhibited] formed a great mass lying right across the abdomen, smooth and rounded in general outline, between two and three inches thick at the thickest part. Sections under the microscope showed that the growth was tuberculous.

Mr CONOLLY NORMAN also exhibited the Stomach and Liver of an old woman who died of phthisis. While under his care she had exhibited no stomachic troubles. The stomach, at a point near the cardia and along the lesser curvature, was firmly adherent to the left lobe of the liver this lobe being small and hard. The site of the adhesion was marked by a firm old cicatrix in the stomach. The lesion was probably of very old standing and was interesting as showing that a perforating ulcer of the stomach is not necessarily fatal.—Mr F. A. NIXON asked if there was any explanation for the statement that tuberculous peritonitis could be cured by abdominal section and drainage of the peritoneal cavity.—Mr J. HARRISON SCOTT said he had seen a case of tuberculous peritonitis cured by that method.

SECTION OF SURGERY

Acute Intestinal Obstruction and its Treatment

A meeting of this Section of Surgery was held on Feb. 24th, Mr NIXON in the chair.

A number of remarkable living and card specimens were exhibited amongst them being a successful case of Ligature of the Innominate, exhibited by Mr COPPINGER, who mentioned the leading facts in connexion with the case. Several members remarked on the extreme interest of the specimens.

Mr Coppinger said he intended to read a paper on the case at some later date.

Mr McARDLE read notes of a case of Laparotomy and free incision of the Sigmoid for Volvulus. The steps in the operation on which he laid stress were First, that the bowel should be incised, not punctured, secondly, that thorough irrigation with warm water should be carried out after incision, not only by passing a tube through the wound in the bowel but by passing a long rectal tube upwards from the anus so as to completely empty the intestinal tract. The third point he laid stress upon was the manner of incising the intestine. Mr McARDLE believed that to evacuate the small intestine a transverse incision is best, whilst the opening should be in a longitudinal direction and in the band of linear fibres opposite the meso-colon when the large intestine is the seat of obstruction. Mr McARDLE gave his reasons for advising this procedure and dwelt on the importance of the complete washing out of the intestine in all cases of obstruction with great distension.

Mr THOMSON thought that in this class of cases the surgeon was greatly handicapped, because in the great majority it was only after undergoing various courses of medical treatment that he was called in. He entirely concurred with the view of Mr McARDLE that they should not wait for the stage of collapse before opening the peritoneum, nor should they accept the doctrine that the peritoneum should not be opened if it was inflamed. In cases of acute intestinal obstruction, as in those of strangulated hernia, he submitted that they could not operate too early. He thought that time was lost by merely puncturing the intestine, and the only true way to deal with such cases was to incise the intestine and evacuate the contents as quickly as possible.

Dr MYLES thoroughly agreed in the great necessity of not merely removing the obstruction, but of emptying the bowel above the obstruction as well. He operated on a patient who had been suffering from obstruction for five days, and on opening the abdomen he found a calculus completely occluding the gut, but he did not douche the bowel above it—a fact which he now regretted. In a case of strangulated hernia he found the inguinal canal patent and in going down into the scrotum he found a volvulus in the hernial sac. He would like to know why tympanites is so fatal in abdominal surgery. In cases of fibroids &c he found the patients developed tympanites, and he confessed that the explanations were not sufficient.

Mr PATTESON said he had the privilege of being associated with Mr McARDLE in this case, and he thought that the result reflected credit on modern surgery. The necessity of early opening was sufficiently proved by the œdema of the meso-colon, to which reference had been made. He attributed the success of this operation to the thorough flushing of the lower part of the intestine, and where the large intestine is involved the colon could be washed out through the rectum.

Dr BALL referred to the futility of relieving the intestines by means of a trocar. If it was tried in the dead house it would be found impossible to evacuate the intestine beyond an inch or two with the trocar. The method of incision was undoubtedly the right procedure. A distended intestine had no more power of recovering its functions than a distended bladder and unless the intestine was emptied before the abdominal wall was closed the operation had only been half completed.

The CHAIRMAN said that, as regards the behaviour of the longitudinal muscular fibres, in a case of laparotomy he made an incision through one of the longitudinal muscular bands and it formed so complete a sphincter that it was necessary to divide it again so as to have an opening there.

Mr McARDLE mentioned that the meso-colon was twisted twice upon itself, so that the meso-colon must have been very long. He believed that exploratory laparotomy should be done more frequently. He would not attempt to explain the tympanites. He agreed with Mr Patteson that the immediate healing and rapid recovery were in a great part due to the thorough irrigation and not alone to the washing out of the intestine, but to washing out the stomach as well.

Reviews and Notices of Books.

Tuberculosis of Bones and Joints By N SENN, M D, Ph D, Professor of Practice of Surgery and Clinical Surgery in Rush Medical College &c Philadelphia and London F A. Davis and Co 1892

THIS is a very valuable monograph. It deals with a subject the interest and importance of which to surgeons are second to none. Our knowledge of tuberculosis has been almost revolutionised since Koch's discovery of the *bacillus tuberculosis*, and, if treatment has not advanced with quite the same giant strides, a perusal of this work will show that great advances have also been made in that department. Dr Senn's method of book making is somewhat peculiar, it consists very largely in collecting together a series of abstracts of, or quotations from, the writings of the "old masters" and the most recent investigators. There is very little of summary or generalisation and not very much of personal experience and opinion. The drawback of this plan is that the reader has to do his own work, it is not done for him, and as he sometimes finds conflicting opinions on the same page without any attempt at reconciling them he is apt to get bewildered. It is not the kind of book for the casual or careless reader. The advantages of Dr Senn's method are, however, very real, the reader gets his information first hand, he is enabled to draw his own conclusions, and to a very large extent sees the facts and not the author's conceptions of those facts.

There is of necessity much repetition in such a book, and we hardly think it requisite to sever so completely, as is here done, tubercle of bones from the same disease in joints. It is unnecessary for us to tell anyone acquainted with Dr Senn as a surgeon or an author that, with few exceptions, he will find only the very newest pathology and the most advanced therapeutics. The pathology is that of the tubercle bacillus, the treatment largely consists in the destruction of this organism. Intra articular and parenchymatous injections of iodoform are spoken of very highly. All surgeons who are called upon to treat cases of this widespread disease should read Dr Senn's book, not only for what it states, but for the full references to the best literature on the subject which it contains, so that if he wishes it the reader can himself pursue the investigation further. Personally we may say that we value the section on Diseases of the Joints more highly than that on Diseases of the Bones, but both are instructive, and having found the book a good one we gladly urge others to test its merits for themselves.

St Thomas's Hospital Reports 1890 New Series. Edited by Dr HADDEN and Mr ANDERSON London J & A Churchill.

THIS volume of reports has been compiled in a manner that reflects great credit on the hospital from which it issues, and it would be well for the profession if a similar one were produced by each of our large institutions for the care of the sick. A full record of the in-patient work is given under the following headings: Medical Report, by Dr H. W. G. Mackenzie, medical registrar, Surgical Report, by Mr E. Solly, surgical registrar, Report of the In-patient Department for Diseases of Women, by Dr C. J. Cullingworth, Report of the Ophthalmic Department, by Mr W. G. Laws, and in the out-patient departments—Report of the Midwifery Department, by Dr Cory, Report on Diseases of the Skin, by Mr L. Scudamore, clinical assistant, Report on the Aural Department, by Mr R. Lake. Only those who have been engaged in compiling statistics of the kind here published can fully appreciate the amount of labour expended in the production of such tables by a conscientious registrar, on whose skill

DENTAL HOSPITAL OF LONDON—At a special meeting of the subscribers to the funds of this hospital the resolution passed at the annual meeting to the effect that the trustees be authorised to apply the general funds to the purchase of a new hospital was confirmed.

will also depend the way in which such abstracts of important cases as are appended to the three principal reports are made. These appear to be too diffuse in the report of the surgical department, which shows some signs of hastiness in preparation and want of care in revision of proofs. For instance, under the heading of Scirrhus of Breast and Glands, we find in the general summary thirteen cases entered with no deaths, but in the special summary at the end of the report two cases are recorded in which operation was performed for that condition, both of which terminated fatally, again, under the heading of Vesical Calculus nine cases are found whilst in the general summary, in a special table under the same heading ten are described. It must surely be a mistake to say that intestine and sac were both excised in a patient suffering from strangulated femoral hernia of only thirteen hours' strangulation. A fact of great importance is shown in the absence of any case of pyæmia arising in the hospital in the surgical wards, one patient unfortunately developed, and died from, that disease in the obstetric ward. Only sixteen cases of erysipelas occurred in the surgical wards and the number of these cases is gradually diminishing from year to year. We have not space to enter into a detailed account of these statistical reports and we have only given this amount of consideration to them because they are above the average in excellence, and we should like to see them approach even more closely the perfection at which they evidently aim.

The earlier, and larger, part of this volume is devoted, first, to obituary notices of former members of the hospital staff or lecturers in the medical school—Dr Thomas A. Barker and Sir J. Risdon Bennett, F.R.S., consulting physicians, Dr W. H. Stone, physician, and Dr Bernays, lecturer on chemistry, and, secondly, to monographs on subjects of interest to the profession. There is a contribution from the pen of the late Mr. Le Gros Clark, F.R.S., on the Sources of Popular Fallacies, and their Influence on Education, the Life History of some Surgical Procedures, by Mr. F. C. Abbott, B.Sc., on Extract of Malt, by Mr. Edmund White, B.Sc., Vegetable Growths as Evidence of Purity or Impurity of Water, by Mr. A. W. Bennett, Cysts of the Jaws by H. Betham Robinson, M.D. M.S., Three Cases of Early Tubal Gestation successfully treated by Abdominal Section, two of the cases after and one before rupture of the tube, by Dr. Cullingworth, Some cases of Removal of the Kidney for Chronic Disease, by Mr. Bernard Pitts, Acute Primary Suppurative Cellulitis of the Neck (Ludwig's Angina), by Dr. Sharkey, a Second Series of Cases of Head jerking in Children with remarks, by Dr. Hadden, Certain Cardiac Symptoms observed in cases of Gastric Ulcer, by Dr. W. M. Ord, a Clinical Lecture on some recent cases of Tuberculous Disease of Bones and Joints in Adults, by Mr. W. Anderson, an Abstract of an Address on some Points of Science and Practice concerning Cancer, delivered in 1877, by Sir John Simon, K.C.B., the Pathology, Course and Symptoms of Pelvic Cellulitis in the Female Sex, by Mr. H. Simpson, Specific Diseases considered with reference to the Laws of Parasitism, by Dr. Payne. Three of the most important contributions to the literature of the profession in this volume, besides that of Dr. Payne, are Tuberculous Peritonitis, its Various Forms, their Surgical Treatment, and Comparative Curability, by Dr. H. P. Hawkins, Albuminuria, and the Condition of the Kneecaps during and after Diphtheria, with tables and cases, by Dr. Mackenzie, and the results of treatment of 322 Compound Fractures of the Long Bones in the Hospital between the years 1881 and 1890 inclusive, by Mr. G. H. Makins and Mr. F. C. Abbott. That these various papers are interesting and of value is attested by the names of the writers. We think it is inadvisable to include in a report for the year 1890 obituary notices of those who have died since that year, and that it is also as a rule a mistake for con-

tributors to write on cases which have come under their observation since the year for which the volume is dated, although a late reference before the volume goes to press will often enhance the value of the record of a case or a report.

A Manual of Veterinary Hygiene By Veterinary Captain F. SMITH, M.R.C.V.S. Second Edition. London: Baillière, Tindall and Cox. 1893.

THE principles of hygiene are being applied to the management and treatment of the domestic animal more sedulously and with greater success than ever and the great benefits this application confers will doubtless in time very much diminish the need for the services of the veterinary surgeon. Within the memory of middle-aged men there has been a heavy reduction in the sickness and loss amongst animals due to diseases arising from the neglect or ignorance of hygienic laws, and this diminution will go on until there will be little but accidents for the veterinary surgeon to deal with. The greater attention paid to this subject is brought all the stronger before us by the comparatively rapid sale of Veterinary Captain Smith's manual, a second edition having been required at the end of six years from its first appearance. When first issued we had the pleasure of commenting favourably upon the work, and we can only repeat what we then stated, and this more especially from the fact mentioned by the author that he has made no alteration in it except a trifling correction in the chapter on ventilation, certainly one of the most important in the book. It may be remarked in reference to the ventilation of stables, especially in large cities where space is so scarce and therefore valuable, that the scheme of ventilation recommended by the author can seldom be carried out to its full extent, and all kinds of devices have to be resorted to in order to provide something like a fair supply of fresh air. A visit to many of the London stables would show how utterly inadequate the ventilation is to meet the requirements of an animal with such largely developed respiratory organs as the horse. No creature more enjoys and requires pure air and perhaps none of the domestic animals is less cared for in this respect. Veterinary Captain Smith's book gives a great amount of information with regard to the preservation of the horse's health and usefulness, and if the principles he enunciates cannot always be carried into practice it is certainly not his fault, but is rather owing to the circumstance that it is only too frequently impossible to adopt them in their entirety, no matter how desirous horse-owners may be so to do.

Advice to Intending Visitors to Cannes By H. BLANC, M.D. London: J. & A. Churchill. 1893.

IN this little work Dr. Blanc gives his impressions of the climate of Cannes and lays down some rules and regulations for the guidance of persons who resort thither. His account of the climate is a little vague and gives his personal impressions rather than definite meteorological statistics. He writes enthusiastically and is of opinion that there are few, if any, better climates in Europe than that of Cannes. We cannot by any means wholly endorse this opinion. Charming as is the natural beauty of Cannes, and many as are its artificial attractions the climate has some serious defects. The winds, especially the mistral, of which Dr. Blanc makes light, are certainly very trying to many invalids; the changes of temperature are somewhat sudden and the net physiological effect of the climate is much too stimulating for many patients. He recommends Cannes to "those in good health who desire a change or wish to avoid the cold and fogs of England and of the north, to convalescents from acute disease, to those whose overworked brain requires rest, to all those who in northern climes suffer from catarrhal affections, to the scrofulous, the lymphatic, the dyspeptic, to children and young adults affected with

tuberculous diseases of the bones, to sufferers from certain forms of phthisis and gout, to the rheumatic, to sufferers from some forms of chronic diseases of the kidneys asthma, functional albuminuria, and the effects of residence in tropical countries.” On the other hand, he thinks “Cannes should be avoided by those suffering from certain nervous affections, by those having a tendency to hemorrhage, those suffering from acute febrile phthisis and those who are prone to attacks of acute gout or eczema.”

LIBRARY TABLE

B Bradshaw's Dictionary of Mineral Waters, Climatic Health Resorts, Sea-baths and Hydropathic Establishments With a Map, printed in colours London Kegan Paul Trench Trübner and Co.—This useful and, in the case of chronic travellers, indispensable dictionary—would not the term Guide be more suitable?—calls for commendation. The information furnished by the book is preceded by chapters headed “Advice to Bathers,” “Hints to Visitors at Watering places” short articles which may be of service to persons who contemplate a brief trip or a more prolonged residence abroad, although in the case of valetudinarians it is always desirable to be guided by the advice of a medical practitioner who knows the circumstances of any particular case rather than to follow implicitly the general directions offered by books. A list of diseases for which the various waters are recommended is given, but of course this kind of information should likewise be accepted subject to the advice of competent medical authority. A table showing the quickest route, mode of conveyance &c., to the different health resorts is followed by an enumeration of the particular kinds of waters to be found in foreign spots. Then comes a list of medical practitioners named in the text and of their summer and winter residences. Finally the reader is presented with a list of “specialists” in London as well as abroad, famed for their skill in the treatment of special diseases. One would like to know by what means the editor was able to appraise the value of the advice and the propriety of the treatment adopted by the specialists named in the book, especially in the case of the London practitioners included in the list. These nominations should be omitted in future editions. A list such as this is, in our opinion most objectionable.

M P's Diary Facts, Ideas Suggestions Reflections and Confessions By JAMES THORNTON HOSKINS, M.A. F.R.S.L. First Series London Digby Long and Co.—We began our consideration of the contents of this volume with an impression so favourable as to awaken in our minds an anticipation of deriving both profit and entertainment from its pages. As we proceeded the impression became confirmed, and the conclusion was finally arrived at that the book was fitted to grace the library of any man of culture. Full of philosophical and psychological reflection, replete with sound deductions, illumined here and there with flashes of genuine humour, the whole based upon wide experience and a large acquaintance with men and things the volume is one that may be taken up at almost any time with profound satisfaction. We meet now and again with a discussion on deeply interesting and important topics, which are dealt with in a critical but at the same time a reverential spirit. Descriptions of mental phenomena, natural and morbid are given with a lucidity which would almost argue the possession by the author of an intimate personal acquaintance with the characteristic phases of those phenomena. A great many theories which have lately come into fashion are directly or incidentally touched upon and, whilst provocative of thought, are discussed in no cavilling fashion but in such a way as to leave the reader in a position to form his own conclusions on the points at issue. We notice a feature in the

book which, from our point of view, must be regarded as a disfigurement—viz., the introduction of names of contemporary medical practitioners in connexion with incidental references to illness in the cases of the author or his friends. Possibly it may not have occurred to him—not being a member of the medical profession—that laudatory notices of the successful treatment carried out by his medical advisers, must have been very distasteful to the professional gentlemen thus favoured. A similar remark may *mutatis mutandis* perhaps be justified with respect to the political bias of the author which is sometimes made unduly prominent in his pages. But that is a point with which we as medical journalists, have no immediate concern. With these reservations we can confidently commend the book to the attention of our readers.

Margate as a Health Resort By H. EVELYN CROOK. M.D. Lond., F.R.C.S. Eng. Margate *Keble's Gazette* Office 1893.—There can be no doubt that Margate possesses some great advantages as a health resort. It has one of the lowest rainfalls in England—viz., 23.31 inches, with 169 days on which rain falls, it has a dry subsoil, a relatively large amount of sunshine, and nearly all the prevailing winds are sea breezes. The drainage has recently been remodelled and is now much more satisfactory than formerly. The death rate is very low—viz., 13.9 per 1000 with a zymotic death rate of only 1.46 per 1000. The climate has a high reputation in scrofula. It is also useful in early phthisis, chronic bronchitis, chronic pleurisy and emphysema, diseases of the heart and some forms of paralysis. These points are well brought out in Dr. Crook's little work.

DISLOCATION OF THE PATELLA “EDGEWAYS”

To the Editors of THE LANCET

SIRS—I am led by the paucity of cases of this kind which have been reported, and which have been successfully treated to bring the following one to the notice of the profession through the medium of the columns of THE LANCET.

Early on the morning of Jan. 9th I was called to attend a labourer, aged eighteen who had ‘put his right knee out of joint’ by falling off the shaft of a waggon. On my arrival I immediately diagnosed the above condition by the peculiar appearance of the knee joint, there being a well-marked ridge with deep depression on either side. The patella was firmly wedged down into the trochlear surface of the femur and the articular facets could be distinctly felt beneath the skin upon the outer side of the limb. On account of the extreme pain caused by attempt at flexion of the knee, or in attempting to lift the patella it was found impossible to reduce without the aid of chloroform, accordingly, help having been procured and the patient having been put under the influence of the drug I tried to reduce by forcibly flexing the knee-joint, as also by lifting the patella, but without avail, so that as a last resource I flexed the hip-joint with the leg perpendicular and firmly pushed the patella downwards in the direction of the hip with the result that it immediately slipped back into its proper position. A back splint was then applied and the knee left bare for the application of cold lotions. The patient was kept in bed for six days and then allowed to get up, when he could walk properly on the splint being removed. The knee was bandaged for a few days when, at his own request he was allowed to return to his work, flexion being normal. I have seen him since several times and he informs me that he is ‘quite well and never feels aught of the knee now, and the knee is perfectly normal.’

I am, Sirs, yours truly

J. T. ROGER MILLER, I.S.A. Lond.,

House Surgeon to the Malton Public Dispensary District Medical Officer for the Leavening District of the Malton Union &c.

THE LANCET.

LONDON SATURDAY, APRIL 1, 1893

THE *Medical Record* of New York of Feb 25th contains a short though interesting paper advocating a less severely antiseptic treatment of puerperal cases than that which is now in vogue and which has certainly diminished in a most gratifying way the mortality of lying in hospitals. To those who are impressed with the physiological character of labour, and who are accustomed to regard the evacuation of the uterus with as much equanimity as the evacuation of the rectum, the necessity of the use of antiseptics before, during and after labour, if pyrexia is to be prevented and the death rate lessened, may seem surprising. Dr WORK, the writer of the paper under consideration, is happily able to say that during the first five years of his professional life 300 pregnant women came under his care, that in no case was there puerperal infection, and in none was the mother disinfected prior to delivery. All are alive so far as he knows, yet the deliveries occurred under the ordinary rough conditions of country practice, in the midst of epidemics of diphtheria, scarlet fever and small pox and it was necessary to treat these and all other diseases common to such practice on the same days, and oftentimes in the same house with, the parturient woman. This is a very happy result, on which Dr WORK is to be congratulated. But we do not think that it should be allowed so to influence the minds of his readers as to produce any relaxation in the use of those measures which have been so conspicuously shown to reduce the rate both of suffering and of death in lying in hospitals, where such sequelæ of confinement had become a scandal so great as to require the temporary closure and almost the abandonment of those institutions. It must be clearly understood that the delivery of a woman and her condition thereafter are by no means such simple questions as the ordinary evacuation of the rectum and the bladder. The bare surfaces left after labour and the acute changes necessitated in the emptied uterus are doubtless physiological conditions, but physiological conditions which border closely on pathological ones and which invite the action of agents whose existence was not suspected a generation back, and whose intense pathogenic activity has been placed beyond all doubt. Herein the special vulnerability of the lying in woman is amply demonstrated and this fact renders all reasonable precautions on the part of her attendants, whether medical or nursing, a most serious duty and the neglect of such precautions an act of inhumanity. No excuse can be offered for the medical man or the nurse who harbours in the nails or in the hands or on the clothes any infection which with extreme cleanliness and care and the use of an antiseptic can be removed or destroyed. We are glad to find that Dr WORK recognises to some extent the antiseptic principle, for he tells us that, in every case he attended, a vaginal injection of warm previously boiled water, with fifteen drops of carbolic acid to the quart, was

insisted upon daily, being first used twenty four hours after delivery and continued up to the cessation of the lochia. The power of aseptic or antiseptic measures is shown not merely in private practice, where parturition has always compared favourably with the same process in lying in hospitals, but in the latter institutions themselves. Dr PRIESTLEY lately showed in a paper read before the Hygienic Congress that in the Maternity Hospital at St. Petersburg, a city where both general and puerperal mortality are high, in a period of three years previously to 1876, by a hygienic discipline almost like that of a prison for the exclusion of infection, and by scrupulous cleanliness, there had been only one death from puerperal fever in the whole establishment, and this was in the case of a woman who was brought to the hospital ill and who died three days after the birth of her child. Antiseptic measures not only almost abolish mortality from puerperal fever, but they reduce to a minimum the risk of the puerperal state and make the occurrence of a rise of temperature in a lying in woman a rare event, an improvement not only for the mother but for the obstetric practitioner, who feels a peculiar responsibility for high temperatures in such cases. In conclusion we must express the hope that "conservatism" will not be too self complacent, and, seeing that each patient should be afforded the highest possible degree of protection from septic poisoning, our opinion that the systematic use of antiseptics should be observed as a matter of routine in every case. It is impossible to over estimate the importance of the thorough disinfection of the hands and nails of practitioners and nurses.

DR. J. S. BILLINGS has recently discussed in the *Forum* the subject of "Medicine as a Career." The key note of his views is struck in the opening sentence, in which he says "To the young man about to choose a professional career medicine at this time offers opportunities for the employment of the highest mental faculties, for the increase of knowledge, for usefulness to the world, and for the attainment of true happiness such as no other profession presents." Companions are always hazardous and frequently futile, so we prefer to leave on one side the question of the merits or demerits of other professions and occupations and follow Dr BILLINGS in so far as his interesting remarks deal simply with the intrinsic advantages, opportunities, and satisfactions of the career of medicine.

The first point in favour of that career is that if the great prizes are few the blanks are also comparatively few. Merit cannot command success with unerring certainty in any pursuit, but it will hardly be denied that merit, moral and intellectual, has as good a prospect of substantial reward in the profession of medicine as in any other great sphere of human activity. Success must not be wholly measured by material results. The most desirable career in life is, as Dr BILLINGS says, one which "has secured a happy home and sufficient means to support it, although it may not have led to wealth, which has brought to its pursuer the approval and friendship of those best acquainted with his life and work, although it may not have made him famous or given him decorations or formal honour, which has made his advice valued and sought for by those who know him although it may not have given him an executive office or

made him a ruler over his fellow men." Such a career, he continues, "does not protect from the afflictions and sorrows common to humanity but it does away in a great measure with boredom and *ennui*, with weary waiting for something to turn up and the work itself is the best resource against inevitable grief. The man who achieves such a career has not been dependent on his acquaintances for his happiness, he has not fretted and worried because his family or his friends or his associates or the State have not recognised his merit according to his conception of it, for he has acted on the principle that he exists for their benefit, and that they are not merely his appendages." Such a result, we rejoice to believe, is capable of attainment by the great majority of the practitioners of medicine and the picture painted in these weighty words is happily no rarity, but of common occurrence.

The second great recommendation of the career of medicine is its suitability for the exercise of the highest powers of the intellect. There never was a time when the highest cosmic and ethical problems were so largely viewed from the standpoint of physics and physiological chemistry as to-day. The nature of the soul, the meaning of the will, the limits of personal responsibility, the laws of healthy psychical as well as physical development, the regulation of marriage, the abatement of crime—on these and on a host of kindred problems it is now universally agreed that the physiologist and the physician must be accorded a most respectful hearing. They may not be able to solve all the difficulties which these great topics raise, but no one seriously questions their competency to afford some of the most important materials for a solution. As Dr BILLINGS happily remarks, "Of all men the skilled physician stands nearest to the veil of Isis, which is becoming thinner though it may never be lifted." The intellectual stimulus of the career of medicine was never greater than to-day. We have achieved much, but we seem to be on the verge of greater discoveries than any that have marked the history of the past. The facts as yet only half understood, relating to such subjects as protection and immunity from disease, inoculation, phagocytosis the natural history of bacteria, brain physiology and many other subjects, open up vistas of illimitable progress and of new scientific methods of the ultimate results of which no man can predict the possible value.

The practical utility of medicine is the next point on which Dr BILLINGS has something to say. "Consider the practical usefulness of medicine. It is not merely physical pain in individuals that is to be lessened or averted. Its results extend far beyond the man whose disability is removed, whose pain is diminished, whose death is delayed, and who is thus enabled to go on with his share of the world's work, they affect the welfare and happiness of his family or his associates, and it may be the interests of a nation, or of the world of science, of literature or of art. It deals also with the health of cities and of nations, with great commercial interests threatened on the one hand with epidemics and on the other by unwise and unnecessary restrictions imposed under the dictates of panic, the offspring of ignorance and cowardice, and its power and possibilities are inextricably involved in many social problems of the gravest importance to modern civilisation." As HERBERT SPENCER justly says the first indispensable condition for the man who wants to play an active and useful part in life is 'to be a good

animal." No doubt now and again a man of very feeble physical powers has achieved great things in art, science or literature, but a few brilliant exceptions must not blind us to the broad general rule that for average men and women and for the average work of the world a fair measure of health and physical vigour is indispensable for usefulness and happiness. The field of the physician may not be quite the highest of fields but it is the most absolutely necessary. If it be ignored and neglected all else will soon get into disorder.

Dr BILLINGS concludes his interesting paper by discussing the demands which the profession of medicine makes on its votaries. Those demands are "for good mental capacity, for a long period of study, for much patience, for powers of honest endurance, for quick and keen sympathies, for honesty and purity of thought, word and deed." He continues "The young man whom I would advise to take medicine as a career should have had a broad preliminary education, he should know his 'humanities,' and it is highly desirable that he should have taken his B.A. degree at a large university, not merely as a guarantee that he has had proper training, but because of the associations which he will have formed there, the ideas which are in the air, the intelligent sympathy with literature, science and art which will there be developed and which is essential to his future usefulness and happiness. He is then to take a four-years course of instruction in a medical school having ample facilities in the way of laboratories and hospitals. Following this should come a service of a year and a half as resident in a large hospital." We are quite in accord with these remarks and only regret that they are beyond the means and opportunities of so many candidates for the profession of medicine. Nothing can be more short-sighted than the present tendency to deprecate a liberal literary and general training as a preliminary to the medical curriculum proper. It is surely better that medical students should begin their professional studies with disciplined and well stored minds than in a state of crude immaturity.

In the recently published number of the Royal London Ophthalmic Hospital reports Dr ALDREN TURNER has an interesting paper in which he describes anomalous conditions of the pupils in various associations. The first group which he describes consists of eight cases all of which exhibited the Argyll Robertson phenomenon, whilst there was no loss of the knee-jerks. In the second series there were two cases exhibiting the same phenomenon, but on one side only, whilst there were no other symptoms of nervous disease. There were also two with symptoms of mixed sclerosis exhibiting a unilateral Argyll Robertson pupil, and one of general paralysis of the insane with the same condition. The third series described comprises two cases, and in these the pupils exhibited the loss of reaction to light, although they still reacted with convergence and there was optic atrophy but no loss of knee-jerks. With reference to these cases, Dr TURNER considers the question of how far the conditions indicate the actual presence of progressive degenerative changes in the central nervous system or the probability of their advent at a later date. The cause of the Argyll Robertson phenomenon is first considered. This may be due to changes

in three situations (1) In the peripheral nervous or muscular apparatus of the iris, (2) in the afferent or efferent limbs of the reflex arc, or (3) in the central mechanism situated in and around the grey matter of the aqueduct of Sylvius—either the antero lateral group of Darkschewitsch, a collection of small cells in the forepart of the oculo-motor nucleus, or in Meynert's system of fibres connecting the oculo motor nuclei with the optic tracts. By a consideration of the various conditions associated with the phenomenon in the different cases the conclusion is reached that the underlying changes were central, and the answer to the inquiry instituted is that the state of the pupil known as the Argyll Robertson phenomenon, existing by itself either on one or on both sides, is highly suggestive of the presence of an early progressive degeneration of the upper portion of the central nervous apparatus, and its presence should lead the observer to suspect the possibility of other symptoms of nervous disease, such as loss of knee jerks, optic atrophy, the presence or history of paralysis of some of the external ocular muscles, or the presence of altered sensibility in the distribution of the nervus trigeminus. Several other cases of interest are related in addition to those already mentioned, and a brief note is added on the oculo facial muscular group. The close association of the frontalis and orbicularis palpebrarum with the ocular movements has been long recognised, and MENDEL has stated the hypothesis that these muscles, although supplied by the facial nerve, are really eye muscles whose central innervation is the oculo motor nucleus. The clinical evidence brought forward in favour of this view consists in the fact that in hemiplegia the upper part of the face escapes, and in the observation long ago made by Sir CHARLES BELL that when a patient with Bell's paralysis is told to shut his eyes, although he may not be able to do so on the affected side, the associated upward rotation of the eyeball takes place, suggestive of a close functional and anatomical relation between that movement and the closure of the eye. Cases of bulbar paralysis also are said to show a striking dissimilarity between the affection of the upper facial muscles and that of the lower ones. If a case of total ophthalmoplegia were observed in which the frontalis and orbicularis palpebrarum were affected whilst the lower facial muscles escaped, the clinical evidence for the hypothesis would be fairly complete. Dr TURNER has not yet seen or heard of such a case. Experimental evidence has been furnished by MENDEL by means of experiments on rabbits after GUDDEN'S method, and the anatomical examination in a case of bulbar paralysis published in a recent number of *Brain* by Dr TURNER and Dr HOWARD TOOTH furnished valuable and important evidence in favour of such a hypothesis. In this case the frontales and orbiculares palpebrarum were intact, the lower facial muscles, on the other hand, being much affected, and the anatomical condition showed, amongst other things, an atrophied condition of the cells of the facial nucleus. The conclusion which the writers arrived at was that there passed, in the trunk of the portio dura nerve, fibres unconnected with the cells of the seventh nucleus to supply the unaffected muscles of the oculo-facial group. The oculo-motor nucleus was quite free from disease. Statements by BOETTIGER, SIMMERLING, MÜLLER and SPITZKA are also adduced in favour of this view, for the firm establishment of which there seems now only to be necessary a case of the crucial character already alluded to.

"Ne quid nlmis."

THE NATIONAL LEPROSY FUND

"It is understood that the London committee of medical and scientific men appointed in connexion with the National Leprosy Fund (of which the Prince of Wales is chairman) have almost completed the consideration of their report. The committee are said to be unable to agree with certain of the recommendations of the Indian Leprosy Commission, notably that relating to the segregation of lepers, it being held that leprosy is not a contagious disease and that segregation would inflict hardship on the patients without securing any advantageous result. It is improbable that the report will be absolutely unanimous, one member of the committee—a distinguished English specialist—being unable to concur with his colleagues as to the advisability of some of the proposed recommendations." The foregoing quotation is taken from *The Times* of March 24th, and is an addition to the far too numerous indications of opinion which have already appeared concerning the still unpublished report of the Leprosy Commission in English, Indian and American journals. Those who are responsible for the management of the affairs of the Leprosy Commission and their report, and for the action of the executive and special committees who have dealt with that report, should, in our opinion, ascertain how it comes to pass that a still unpublished document and the comments, which have, it is said, been made about it in committee, are discussed, from time to time, in an apparently authoritative way by some journals, when it is certain that if these statements have any foundation in fact they must have been communicated to them, either directly or indirectly, by someone who has spoken of that which he ought to have kept secret. For our own part, we have refrained from entering upon this subject of the report of the Leprosy Commissioners, because many months ago we received an assurance from the highest official source that no authorised statements touching this report, or the opinions expressed concerning it in the English committees, would be made public until it and all official documents relating to it were ready for simultaneous publication here and in India. These documents and the report are not yet ready, we are assured, to leave the publisher's hands both here and in India, and, therefore, no statement concerning the latter can be other than unauthorised.

DISPARAGEMENT OF HOSPITALS AT NEWCASTLE

WHATEVER the faults of hospital administration may be, these institutions are so indispensable that they should be criticised with due notice and in a friendly spirit. The *Newcastle Daily Chronicle* contains the report of a special meeting of the city council to consider the estimates of income and expenditure for the year. Amongst others was an item of £1240, which as surplus ought, as has been the custom of the council, to be divided amongst the charitable and learned institutions of the city. Of this sum £350 was assigned to the Newcastle Infirmary. Mr Anderson proposed to delete this item unless one or two representatives of the council were put on the infirmary board. Alderman Newton, a member of the medical profession, made a still more ungracious attack on the proposal, urging that any surplus should go to the reduction of the municipal expenses and adding that "the infirmary was run more for the advantage of the medical and surgical staffs than in the interests of the poor people who used it. These doctors divided amongst them £2000." He moved that the sum of

£12-0 be deleted from the estimates. When a medical man talks thus it is apt to be taken seriously. Fortunately Alderman Newton was well answered by Alderman Stephenson and by Alderman Stephens, the former saying that the donation was one of the unwritten laws of the council, which it would be unkind and ungenerous to break without notice, the latter gentleman showed that the moneys received by the medical staff were paid by students for lectures and that if the council paid the infirmar £560 instead of £350 it would be nearer meeting the expense to which it put the infirmary. The completeness of the answer was recognised by the council, who rejected the motion by 23 to 5. Alderman Stephenson pointed out that the council was represented on the infirmary board by the mayor and Alderman Stephens, but the council agreed to a letter asking for a larger representation.

DEATH OF A DENTIST FROM NITROUS OXIDE GAS

AN inquest was held by Mr C Luxmore Drew at the Chelsea Town Hall concerning the death of Mr Thomas Samuel Minett, aged forty years, a dentist in practice in Sloane-street. It appears that the deceased was discovered by his assistant seated on a chair in a corner of his surgery with his head and body bent forwards and his mouth covered by the mouth piece of a nitrous oxide apparatus. When Dr Herbert Gage-Brown, who was immediately summoned, saw Mr Minett the body was warm, there was no pulse, and he tried artificial respiration without avail. The body was at that time laid upon the floor. The gas apparatus consisted of two bottles of 100 gallons each fixed vertically on a stand with a hand key, and were in communication with the face-piece by means of an india-rubber tube with a two gallon bag intervening. One bottle, that to which the key was applied, was empty and the tap turned full on, as was also the stopcock of the face-piece, the other was turned off securely. The post mortem examination revealed only the usual symptoms of asphyxia, all the organs were normal, with the exception of some slight hypertrophy of the heart, the trachea was freely opened and no foreign body was present. The question naturally arises: Was this death due to nitrous oxide gas inhaled for too long a time? Dr Gage-Brown will, we believe, shortly bring before the notice of the profession a full account of this interesting case, we therefore defer any detailed comment, but it seems quite within the bounds of possibility that a man sitting in a chair and taking a whiff or two of gas, to see, for instance, whether the apparatus was all right, might fall forward with his arm supported on his knee or chair, the face-piece being thus kept in position till death resulted. The jury returned a verdict of "Death by Misadventure."

SANITATION AT MENTONE

THE hotel keepers at Mentone are to be congratulated on the intelligent energy and enterprise they have displayed. It had long been felt that many sanitary measures should be taken to render the town a satisfactory health resort. The want of proper means of disinfection, amongst other requirements, was the cause of inconvenience and anxiety. Nevertheless the municipality under the pretext of financial difficulties did not move in the matter. Wearied of raising the majority of the hotel keepers of Mentone formed themselves into a syndicate. Each member paid an entrance fee in proportion to the importance of his hotel—namely seven francs for each room, and an annual subscription of one franc per room. With the moneys thus obtained the most improved disinfecting stove was purchased, a mechanic was employed to manage it and a *lecce* hired for disinfecting purposes. The whole installation cost £3-0. The medical profession were requested to report all cases of zymotic disease and of phthisis to the

mayor. The syndicate undertook to disinfect for soldiers and for poor people gratuitously, those who can afford to pay are charged a moderate fee. All carpets, bedding, clothes &c. are removed to the stove and exposed to the action of steam superheated under pressure. Articles of furniture, chairs, sofas &c. are placed in a fumigation room and disinfected by sulphuric acid gas. The bare room is then sprayed all over with a solution of sublimite. The Syndicate of Hotel-keepers was formed three years ago, and already the practice of disinfection has become general throughout the town. Indeed the fees collected for disinfecting exceed considerably the cost of maintaining the apparatus and the staff of disinfectors, thus proving that the municipality might have undertaken the work without increasing its financial difficulties. The municipality has, however, helped in every possible way and allows the syndicate of hotel keepers the free use of an abandoned slaughterhouse, which has now been converted into the disinfecting station. Further than this, the syndicate has been the means of bringing most hotels up to the same level of sanitary progress. Now nearly all the hotels have proper closets well trapped, ventilated and flushed, an advantage which English travellers on the Continent will greatly appreciate.

THE LATE DR CECCARELLI

THE judicial authorities according to the *Osservatore Romano*, received certain anonymous communications in terms of which Dr Ceccarelli had been "removed" by poison. The instant this charge became known Professor Lapponi, assistant to Dr. Ceccarelli and the responsible physician in attendance on his ailing chief came forward and gave a categorical denial to the said charge, reinforcing his testimony with that of the other three eminent physicians whom he had called in consultation. Notwithstanding this authoritative declaration the President of the Court of First Instance ordered the immediate exhumation of Dr Ceccarelli's body and caused the alimentary tract to be minutely examined by the experts of the court with a view to the detection of the supposed poison. The result of this examination was to confirm in every point Dr Lapponi's diagnosis embodied in the death certificate, according to which Dr Ceccarelli died of peritonitis supervening on intestinal ulceration induced by catarrh. "Thus," says the official organ of the Vatican, "collapses the ridiculous fabrication put together by an unknown hand for an unknown object—a fabrication to which the judicial authorities with incredible want of consideration, lent a weight to which it had absolutely no title." Other journals, commenting on the incident take a similar view with the *Osservatore Romano* whilst more than one of them hazard the surmise that the false report was set on foot by some disappointed "legacy hunter" in Dr Ceccarelli's entourage who resented the application of so much of the doctor's patrimony to charitable and professional objects instead of to the personal advantage of the legacy hunter in question.

THE INTERNATIONAL MEDICAL CONGRESS

AN Italian correspondent writes under date Rome, March 24th—To last week's announcements I have to add an intimation from the Central or Organising Committee of the Congress that it continues to receive from medical schools abroad a steady influx of *adonors* (pledges). Within the last few days the Hungarian Minister of the Interior has notified, in an autograph letter addressed to Dr Guido Baccelli, President of the Committee, that Hungary will be represented at the Congress by her medical councillor Dr Cornelius Thyzer, and by Dr Samuel Papp, member of the Chamber of Deputies. The Minister of Public Instruction in the same kingdom has also written to say that his delegate will be Dr Ludwig Toth of the Medical Faculty

in three situations (1) In the peripheral nervous or muscular apparatus of the iris, (2) in the afferent or efferent limbs of the reflex arc, or (3) in the central mechanism situated in and around the grey matter of the aqueduct of Sylvius—either the antero lateral group of Darlschewitsch, a collection of small cells in the forepart of the oculo motor nucleus, or in Meynert's system of fibres connecting the oculo-motor nuclei with the optic tracts. By a consideration of the various conditions associated with the phenomenon in the different cases the conclusion is reached that the underlying changes were central, and the answer to the inquiry instituted is that the state of the pupil known as the Argyll Robertson phenomenon, existing by itself either on one or on both sides, is highly suggestive of the presence of an early progressive degeneration of the upper portion of the central nervous apparatus, and its presence should lead the observer to suspect the possibility of other symptoms of nervous disease, such as loss of knee-jerks, optic atrophy, the presence or history of paralysis of some of the external ocular muscles, or the presence of altered sensibility in the distribution of the nervus trigeminus. Several other cases of interest are related in addition to those already mentioned, and a brief note is added on the oculo facial muscular group. The close association of the frontalis and orbicularis palpebrarum with the ocular movements has been long recognised, and MENDEL has stated the hypothesis that these muscles, although supplied by the facial nerve, are really eye muscles whose central innervation is the oculo-motor nucleus. The clinical evidence brought forward in favour of this view consists in the fact that in hemiplegia the upper part of the face escapes, and in the observation long ago made by Sir CHARLES BELL that when a patient with Bell's paralysis is told to shut his eyes, although he may not be able to do so on the affected side, the associated upward rotation of the eyeball takes place, suggestive of a close functional and anatomical relation between that movement and the closure of the eye. Cases of bulbar paralysis also are said to show a striking dissimilarity between the affection of the upper facial muscles and that of the lower ones. If a case of total ophthalmoplegia were observed in which the frontalis and orbicularis palpebrarum were affected whilst the lower facial muscles escaped, the clinical evidence for the hypothesis would be fairly complete. Dr TURNER has not yet seen or heard of such a case. Experimental evidence has been furnished by MENDEL by means of experiments on rabbits after GUDDEN's method, and the anatomical examination in a case of bulbar paralysis published in a recent number of *Brain* by Dr TURNER and Dr HOWARD TOOTH furnished valuable and important evidence in favour of such a hypothesis. In this case the frontales and orbiculares palpebrarum were intact, the lower facial muscles, on the other hand, being much affected, and the anatomical condition showed, amongst other things, an atrophied condition of the cells of the facial nucleus. The conclusion which the writers arrived at was that there passed, in the trunk of the portio dura nerve, fibres unconnected with the cells of the seventh nucleus to supply the unaffected muscles of the oculo-facial group. The oculo-motor nucleus was quite free from disease. The municipality has, however, helped in every possible way and allows the syndicate of hotel keepers the free use of an abandoned slaughterhouse, which has now been converted into the disinfecting station. Further than this the syndicate has been the means of bringing most hotels up to the same level of sanitary progress. Now nearly all the hotels have proper closets, well trapped, ventilated and flushed, an advantage which English travellers on the Continent will greatly appreciate.

THE LATE DR CECCARELLI

THE judicial authorities, according to the *Osservatore Romano*, received certain anonymous communications, in terms of which Dr Ceccarelli had been "removed" by poison. The instant this charge became known Professor Laponi, assistant to Dr Ceccarelli and the responsible physician in attendance on his ailing chief came forward and gave a categorical denial to the said charge, reinforcing his testimony with that of the other three eminent physicians whom he had called in consultation. Notwithstanding this authoritative declaration the President of the Court of First Instance ordered the immediate exhumation of Dr Ceccarelli's body and caused the alimentary tract to be minutely examined by the experts of the court with a view to the detection of the supposed poison. The result of this examination was to confirm in every point Dr Laponi's diagnosis embodied in the death certificate, according to which Dr Ceccarelli "died of peritonitis supervening on intestinal ulceration induced by catarrh." "Thus," says the official organ of the Vatican, "collapses the ridiculous fabrication put together by an unknown hand for an unknown object—a fabrication to which the judicial authorities, with incredible want of consideration, lent a weight to which it had absolutely no title." Other journals, commenting on the incident take a similar view with the *Osservatore Romano* whilst more than one of them hazard the surmise that the false report was set on foot by some disappointed "legacy hunter" in Dr Ceccarelli's *entourage* who resented the application of so much of the doctor's patrimony to charitable and professional objects, instead of to the personal advantage of the legacy hunter in question.

THE INTERNATIONAL MEDICAL CONGRESS

AN Italian correspondent writes under date Rome, March 24th—"To last week's announcements I have to add an intimation from the Central or Organising Committee of the Congress that it continues to receive from medical schools abroad a steady influx of *adesioni* (pledges). Within the last few days the Hungarian Minister of the Interior has notified, in an autograph letter addressed to Dr Guido Baccelli, President of the Committee, that Hungary will be represented at the Congress by her medical councillor Dr Cornelius Thyzer and by Dr Samuel Papp, member of the Chamber of Deputies. The Minister of Public Instruction in the same kingdom has also written to say that his delegate will be Dr Ludwig Toth of the Medical Faculty

in three situations (1) In the peripheral nervous or muscular apparatus of the iris, (2) in the afferent or efferent limbs of the reflex arc, or (3) in the central mechanism situated in and around the grey matter of the aqueduct of Sylvius—either the antero lateral group of Darkschewitsch, a collection of small cells in the forepart of the oculo-motor nucleus, or in Meynert's system of fibres connecting the oculo-motor nuclei with the optic tracts. By a consideration of the various conditions associated with the phenomenon in the different cases the conclusion is reached that the underlying changes were central, and the answer to the inquiry instituted is that the state of the pupil known as the Argyll Robertson phenomenon, existing by itself either on one or on both sides, is highly suggestive of the presence of an early progressive degeneration of the upper portion of the central nervous apparatus, and its presence should lead the observer to suspect the possibility of other symptoms of nervous disease, such as loss of knee-jerks, optic atrophy, the presence or history of paralysis of some of the external ocular muscles, or the presence of altered sensibility in the distribution of the nervus trigeminus. Several other cases of interest are related in addition to those already mentioned, and a brief note is added on the oculo-facial muscular group. The close association of the frontalis and orbicularis palpebrarum with the ocular movements has been long recognised, and MENDEL has stated the hypothesis that these muscles, although supplied by the facial nerve, are really eye muscles whose central innervation is the oculo-motor nucleus. The clinical evidence brought forward in favour of this view consists in the fact that in hemiplegia the upper part of the face escapes, and in the observation long ago made by Sir CHARLES BELL that when a patient with Bell's paralysis is told to shut his eyes, although he may not be able to do so on the affected side, the associated upward rotation of the eyeball takes place, suggestive of a close functional and anatomical relation between that movement and the closure of the eye. Cases of bulbar paralysis also are said to show a striking dissimilarity between the affection of the upper facial muscles and that of the lower ones. If a case of total ophthalmoplegia were observed in which the frontalis and orbicularis palpebrarum were affected whilst the lower facial muscles escaped, the clinical evidence for the hypothesis would be fairly complete. Dr TURNER has not yet seen or heard of such a case. Experimental evidence has been furnished by MENDEL by means of experiments on rabbits after GUDDEN'S method, and the anatomical examination in a case of bulbar paralysis published in a recent number of *Brain* by Dr TURNER and Dr HOWARD TOOTH furnished valuable and important evidence in favour of such a hypothesis. In this case the frontales and orbiculares palpebrarum were intact, the lower facial muscles, on the other hand, being much affected, and the anatomical condition showed, amongst other things, an atrophied condition of the cells of the facial nucleus. The conclusion which the writers arrived at was that there passed, in the trunk of the portio dura nerve, fibres unconnected with the cells of the seventh nucleus to supply the unaffected muscles of the oculo-facial group. The oculo-motor nucleus was quite free from disease. Statements by BOETTIGER, SIEMERLING, MÜLLER and SPITZKA are also adduced in favour of this view, for the firm establishment of which there seems now only to be necessary a case of the crucial character already alluded to.

Annotations.

"No quid nimis."

THE NATIONAL LEPROSY FUND

"It is understood that the London committee of medical and scientific men appointed in connexion with the National Leprosy Fund (of which the Prince of Wales is chairman) have almost completed the consideration of their report. The committee are said to be unable to agree with certain of the recommendations of the Indian Leprosy Commission, notably that relating to the segregation of lepers, it being held that leprosy is not a contagious disease and that segregation would inflict hardship on the patients without securing any advantageous result. It is improbable that the report will be absolutely unanimous, one member of the committee—a distinguished English specialist—being unable to concur with his colleagues as to the advisability of some of the proposed recommendations." The foregoing quotation is taken from *The Times* of March 24th, and is an addition to the far too numerous indications of opinion which have already appeared concerning the still unpublished report of the Leprosy Commission in English, Indian and American journals. Those who are responsible for the management of the affairs of the Leprosy Commission and their report, and for the action of the executive and special committees who have dealt with that report, should, in our opinion, ascertain how it comes to pass that a still unpublished document and the comments, which have, it is said, been made about it in committee, are discussed, from time to time, in an apparently authoritative way by some journals, when it is certain that if these statements have any foundation in fact they must have been communicated to them, either directly or indirectly, by someone who has spoken of that which he ought to have kept secret. For our own part, we have refrained from entering upon this subject of the report of the Leprosy Commissioners, because many months ago we received an assurance from the highest official source that no authorised statements touching this report, or the opinions expressed concerning it in the English committees, would be made public until it and all official documents relating to it were ready for simultaneous publication here and in India. Those documents and the report are not yet ready, we are assured, to leave the publisher's hands both here and in India, and, therefore, no statement concerning the latter can be other than unauthorised.

DISPARAGEMENT OF HOSPITALS AT NEWCASTLE

WHATEVER the faults of hospital administration may be, these institutions are so indispensable that they should be criticised with due notice and in a friendly spirit. The *Newcastle Daily Chronicle* contains the report of a special meeting of the city council to consider the estimates of income and expenditure for the year. Amongst others was an item of £1240, which as surplus ought, as has been the custom of the council, to be divided amongst the charitable and learned institutions of the city. Of this sum £350 was assigned to the Newcastle Infirmary. Mr Anderson proposed to delete this item unless one or two representatives of the council were put on the infirmary board. Alderman Newton, a member of the medical profession, made a still more ungracious attack on the proposal, urging that any surplus should go to the reduction of the municipal expenses and adding that "the infirmary was run more for the advantage of the medical and surgical staffs than in the interests of the poor people who used it. These doctors divided amongst them £2000." He moved that the sum of

that have been tried from time to time. The exact make of the silk is another detail. Should it be Chinese twist, or floss silk? For the latter it is claimed by Dr. Spencer that it is both cleaner, and that it can be tied more tightly. It is certainly a mistake to use very thick silk with the view of avoiding breaking of the ligature. This is to be prevented rather by taking care not to jerk the ligature as it is being tied. On the other hand, too thin a ligature is more likely itself to break and to cut the tissues. A medium size is best. The general opinion did not bear out the suggestion that boiling the silk in carbolic lotion weakened it, and the advantages of this process are obvious. The three principal methods of tying the ligature after transfixing are (1) to cut the loop and tie the pedicle in two halves after crossing the ligatures, (2) the Staffordshire knot, and (3) to pass one free end round the pedicle, through the loop, and so on till it meets the other free end, and then tie. Whilst all three methods, properly managed, are good, the last is the simplest. With the first operators even of considerable experience may at times spend some seconds in ascertaining which end is the one they want. When the pedicle is thick it is certainly a good plan to hold the knot after the first hitch with pressure forceps whilst the second hitch is being tied, and when the pedicle is very broad it is an additional safe guard to tie the ovarian vessels by a separate ligature.

HARSH CONDUCT OF WORKHOUSE ATTENDANTS

ROUTINE and custom have each doubtless a legitimate place in every system of administration and it must occasionally happen that severe measures have to be employed in support of established rule. These observations it must also be allowed, will apply no less within the walls of the workhouse than elsewhere if the essential condition of order is to be maintained. It is at all times needful, however, that custom should be instructed by intelligence, and that a regard for discipline on the part of officials should not be allowed to blind them to the prior claims of humanity. The following cases tend to strengthen a belief that there are some persons of this class whose preference for a rough and ready method is too little controlled by better and milder considerations. In one instance a 'refractory' inmate of a London workhouse had offended by objecting to rise daily at 4 A.M. and to sit by an open window whilst his bed was made. It mattered not apparently that he was suffering from chronic phthisis. The rule required that he should rise and be chilled as above described and rise he must, and he could not be exempted from existing ward regulations. We may take it that his condition of health was not at the time critical. Nevertheless the unwisdom and harshness of thus exposing him whilst even weak is manifest. In another case elsewhere a boy was, out of mere spite, scalded to death with carbolic acid by an attendant who is now very properly expiating his cruel offence in prison. Such incidents as these cannot tend to foster public confidence in our parochial management. We fully believe that there are to be considered as exceptions to a better rule of justice and humanity which, on the whole, is faithfully observed. The recital of them reads badly notwithstanding and it is to be hoped that the responsible authorities will note this and will exert themselves to repress all such needless or wanton harshness on the part of officials.

SMALL-POX IN LONDON

THE circumstances under which small pox is being disseminated in London by the inmates of common lodging houses, casual wards and Salvation Army shelters has been matter of report to the London County Council and its medical officers and has been pointed out by the Metropolitan Asylums Board. Attention has also been directed to the same subject by Dr. Waldo, the medical officer of health of the parish of St. George the Martyr, who, on March 14th,

reported to the sanitary authority that of three cases of small pox two lived in common lodging-houses and one was an inmate of the St. George's Workhouse in Mint-street. The two former cases were detected by the medical officers at the relief station in the Borough High street and at Guy's Hospital. Dr. Waldo has traced some cases to the Salvation Army shelter in the Blackfriars-road, where they were living during the probable period of infection and for some time previously. He states that he has also received further information from medical officers of health and others of further cases of small pox presumably contracted at the same Salvation Army shelter, and he expresses the opinion that the spread of the disease might be largely curtailed if the Union medical officers would generally follow the good example set them in this parish and make a rule of inspecting all casuals before they leave the workhouse. Dr. Waldo believes the time has arrived for England to follow the example of Germany and make revaccination compulsory. Unfortunately at the present time the tendency is to relax the enforcement of the law requiring the vaccination of infants. It is therefore very difficult to believe that a proposal that revaccination should be made obligatory is likely to be entertained either by the Vaccination Commission or by Parliament. It is, however, possible for every head of a family to ensure that his household is protected against small pox, and as to those who rely on such protection as isolation of the sick in hospital can give we can only hope that the increasing difficulty attending the provision of small pox hospitals will have some weight in inducing them to rely upon vaccination. Certainly it is unfair to burden the well vaccinated with the cost of hospital provision necessary only for those who are negligent of vaccination.

SODA WATER SAYS SODA

A QUESTION of considerable importance and concern to the mineral water industry was decided at the West London Police Court last week. It was proved that soda water had been purchased by an inspector at two public houses which, under the provisions of the Sale of Food and Drugs Act, was not of the nature and substance demanded, in other words it was simply aerated or carbonated water and contained no soda. The magistrate said it could not be regarded as soda water, as there was no soda in it, it should be sold under the name of carbonated water. He therefore imposed a penalty with costs. Since mineral water making has been an industry it has been well known that ordinary soda water is rarely anything else than a simple solution of carbonic acid gas in water under pressure. In fact true soda water is an official preparation the liquor sodæ effervescens of the British Pharmacopœia, containing a definite quantity (CO grains to the pint) of the bicarbonate. It may therefore, be viewed as a medicinal agent, an antacid whereas the plain carbonated water is only a common beverage. It is safe to assert that by far the greater quantity of soda water is consumed as a beverage, and to substitute another name for it therefore, such as carbonated water would only introduce a good deal of unnecessary confusion. Of course if soda water B.P. is especially required it should be ordered and only then should true soda water be supplied. We do not see how the old name can now be changed, it would inflict certain hardships and a large amount of inconvenience upon the trade and the public. Would it not be enough if the trade were in future to adopt the use of the letters B.P. when real soda water is meant? Real soda water however being of the nature of a drug should, when specially required, be obtained from the chemist or direct from the manufacturers and certainly not from the publican. Probably most of, if not all, the soda water obtained at the bars of restaurants and other places of refreshment is 'soda water' and soda. If the term 'a brandy for whiskey' and

of the University of Budapest, whilst the Croatian Government will be represented by Dr Stappi. The Superior Board of Health of Hungary has also deputed as its commissioners at the Congress four heads of departments in State medicine to wit, Dr Ludwig De Csatory, Dr Josef Fodor, Dr Karl Retly, and Dr Abram Sonntag. From the Medical Faculty of the University of New York comes the announcement that it will shortly proceed to nominate its delegates to the Congress, and from the National Committee of Mexico a similar intimation that its chief medical schools will also be represented. For the greater convenience of the 'Congressists' the Central Committee, through its executive department, has arranged that the 'special counters' (*tessere speciali*) entitling the said 'Congressists' with their wives or daughters to a reduction of steamboat or railway fares will be distributed by the committees of their respective nationalities. The managers of more than one British railway (the Great Eastern, for example) will issue to the 'congressists' special tickets by which, on payment of his fare at the point of departure, the holder will make the return journey free of charge. One word more as to the 'Esposizione di Medicina ed Igiene,' which will be open from Sept. 15th till at least the middle of October. Its organising committee (President, Professor Paghani) announces that 'permits' entitling houses and firms to exhibit their wares are in much request, particularly from abroad, and that no time should be lost in forwarding consignments to their appropriate sections. The exhibition of recent additions to the United States' Pharmacopœia will, I understand, be at once typical and exhaustive."

SMALL-POX IN SCOTLAND

GLASGOW continues to be the chief centre of the disease, but though the cases have increased during the past fortnight the medical officers have not yet given up hope of being able to stem the outbreak. During the week ending March 18th there were 30 new cases and in the following week 16, the number in hospital on March 24th being 93. From Saturday till Tuesday last 5 new cases were reported. At Edinburgh the epidemic does not make headway, though one new case was reported recently and the number in the Canongate Hospital was 16. In Dundee there were no cases from March 12th to 24th, when two more occurred. Revaccination continues to be taken free advantage of. In Paisley the seventh case occurred within the burgh fully ten days ago. In the Vale of Leven, which had hitherto remained entirely free from the disease, 5 cases have appeared simultaneously in different localities and have been removed to hospital. In Castle Douglas, in a family of six persons, 5 have been attacked. Single cases are also reported from Boness, Dregburn, Irvine and the neighbourhood of Aberfoyle in Perthshire, the patient here being a navy on the Glasgow waterworks tract.

THE DUTIES AND PRIVILEGES OF NURSES

DR. LEDIARD of Carlisle has recently delivered a series of lectures on nursing. In his concluding address a prominent place was given to the consideration of hysteria and its appropriate modes of treatment. We pass over the details of symptoms which are universally familiar to consider briefly the lecturer's clear and practical observations on the causation and treatment of this troublesome condition. Probably we could hardly better describe its essential character than by quoting his own expression and regarding it as a "back ground" of hereditary neurotic tendency upon which a variety of complaints may be painted. These, he reminds us, are of truly morbid character and not merely imaginary. Underlying all is the fundamental weakness implied in an untrained and unstable will, and the first aim of all remedial action employed in cases of the kind must be to regulate and strengthen this erratic

faculty. Healthy activity of body must be promoted by physical exercise, three volume novels and afternoon teas being relegated to a quite subordinate position. The mind in like manner must be trained by employing knowledge and directness of purpose to stamp out an ignorance which results in objectless existence. By a natural transition to the practice of these precepts Dr Lediard proceeded to describe in terms of cordial commendation the duties and privileges of the nursing vocation. He reminded his hearers that their calling is no mere occupation, but a trust, the possession of which is an honour to womanhood. Enthusiasm and sympathy combined with intelligent observation were in its exercise the true guarantees of success, which in this case must be judged, not by conspicuous recognition, not always even by the accomplishment of the individual nurse's intended purpose, but by the proofs of duty patiently discharged and a gain of experience which might leave her profession the better because she had belonged to it.

DEATH OF A MEDICAL STUDENT FROM SEPTIC POISONING

WE regret to record the death of a student of the London Hospital from disease contracted in the discharge of his duties. Mr Nathaniel D S Towne came of a good medical stock, his father and grandfather having practised in Stoke Newington, where the family is widely known and esteemed. Mr N D S Towne entered as a student at the London Hospital in 1889, and was consequently in his fifth year of study. He had passed his first two examinations at the Conjoint Board and would soon have presented himself for the final examination. He was at the time of his death a clinical and post mortem clerk. About three weeks ago he poisoned his finger either in dressing an empyema or in the post-mortem room. A small abscess under the nail resulted and, following this, an abscess in the axilla, with a severe rigor. The axillary abscess was opened, but a high degree of pyrexia persisted and, later, further suppuration occurred in the axilla. As the result of this, profuse venous hæmorrhage took place, which was arrested with great difficulty. The pyrexia continued and exhaustion followed, leading to Mr Towne's death on March 19th. Mr Towne was a specimen of all that is best in the medical student—enthusiastic in his love of work, keen, punctual and conscientious in the discharge of his duties, regular and methodical in his studies, pure in his conduct, bright and genial in his disposition. His father, who died five years ago, was one of those self sacrificing and earnest members of our profession who earned not only the gratitude and respect of their patients, but, what is more rare, their affection. Mr Towne seemed, from the characteristics he had already displayed, destined to follow in his father's footsteps when cut down in the prime of his youth. Death is sad at most times, especially, however, is it sad in the young. This death is an illustration of the risks of our profession, not only in the actual discharge of duty, but in the necessary preparatory education.

LIGATURE OF THE PEDICLE IN OVARIOTOMY

IN the discussion on Mr Doran's paper at the last meeting of the Obstetrical Society of London there was a general agreement that the best method of treating the pedicle in ovariectomy and similar cases is usually by means of the ligature. Here and there, we believe, the method of securing the pedicle by the clamp and cautery is still practised, but the ligature has been adopted almost universally by the large majority of operators. As to several points of detail, however, there is still some difference of opinion. Thus as to the material for the ligature, its thickness and the kind of knot in which it should be tied, there is less agreement than might have been expected. Most authorities agree in preferring silk to kangaroo tendon, chromic gut, or the other substances

remainder consisted of 57 children, of whom 7 were vaccinated and 50 unvaccinated. The age incidence and the fatality in respect to the vaccination conditions are very instructive.

SANITARY IMPROVEMENTS IN OBAN

At a meeting of the Oban Town Council held on February 20th last, an able and exhaustive report was submitted by Dr Baily, the Medical Officer of Health. After pointing out the insanitary condition of certain properties, due either to insufficiency or total absence of drainage arrangements, and suggesting means for their correction Dr Baily pressed upon his sanitary authority the advisability of adopting a system of registration and certification of houses, such as we proposed in the report of our Commission on Sanitation in Relation to the Law and Practice of House Letting published in August, 1892, and which has already proved successful at Eastbourne, Folkestone and other towns. Dr Baily also urged the necessity of including measles under the Notification of Infectious Diseases Act and the importance of the sanitary authority providing not only a permanent building for the treatment of infectious diseases, but also a temporary hut hospital in the event of the unwelcome visitor, cholera, invading our shores in the summer. We are glad to be able to state that the Town Council has acquiesced in the wisdom of the recommendations of its medical officer of health by adopting both the plan of registration and certification of houses and the inclusion of measles under the Notification Act, whilst the provision of further hospital accommodation is also under consideration. Oban is a favourite resort of tourists from all parts of the British Isles during the summer, and it forms a central point from which holiday makers set out to visit the Western Highlands. It must, therefore, be obvious how closely dependent the prosperity of such a town must be upon its public health, and, whilst we congratulate the Town Council upon the enlightened policy on which they have embarked, we feel sure that such policy will materially increase the favour in which Oban is already held as a holiday resort.

FOREIGN UNIVERSITY INTELLIGENCE.

Basle—Dr Carl Haegler has been recognised as *privat-docent* in Bacteriology and Surgery.

Berlin—Drs E Grawitz, Paul Heymann and Hugo Neumann have been recognised as *privat-docenten* in Medicine, Laryngology and Children's Diseases respectively. Dr Franz Hilgendorf, Custos of the Zoological Museum, has been granted the title of Professor. Dr Paul Glan, who is well known by his invention of the spectro-photometer, has been promoted to an Extraordinary Professorship of Physics in the Philosophical Faculty. Professor Hamaan, who was formerly in Göttingen, has been recognised as *privat-docent* in Zoology.

Genoa—Dr Maurice Bourcart has been recognised as *privat-docent* in Midwifery and Gynaecology.

Harana—Dr Rafael Molla of Madrid has been appointed Professor of Clinical Surgery.

Karkoff—Dr T J Bogolomoff of St. Petersburg has been appointed to the Professorship of Medical Chemistry in succession to Dr Danielevski, who has gone to St. Petersburg.

Kieff—Dr V P Obrazmoff has been appointed to the Professorship of Special Pathology and Therapeutics. At the recent examination for the diploma of *Irach* (Medical Practitioner) sixty-five candidates presented themselves, of whom fifty-nine passed—twenty-four *cum eximia laude*.

Leprie—Drs Lenhartz, Karg and Döderlein have been promoted to Extraordinary Professorships of Medicine, Surgery and Midwifery respectively. Dr Urban has been recognised as *privat-docent* in Surgery.

Moscow—In the recent examinations for the diploma of Medical Practitioner there were 212 candidates, 191 of whom passed—13 with distinction.

Munich—Dr Barlow has been recognised as *privat-docent* in Dermatology and Dr Siegfried Molher as *privat-docent* in Anatomy.

Naples—Dr A. Pasquale has been recognised as *privat-docent* in Hygiene.

New York (Polyclinic)—Dr Florian Krug has been appointed Professor of Gynaecology. Dr E Dench Professor of Otolaryngology, Dr Katzenbach Professor of General Pathology, and Dr J Adler Professor of Clinical Pathology.

Strasbourg—Dr Pfitzner has been promoted to the chair of Topographic Anatomy in succession to Dr Joessel, deceased.

St. Petersburg—Lectures on Cholera have been arranged for students of all faculties so that those who may be employed in any administrative duty may be the better prepared to combat a recrudescence of the epidemic. As the University has no medical faculty, six *privat-docenten* from the Military Medico-Chirurgical Academy have been selected to give the lectures.

St. Petersburg (Military Medical Academy)—Drs Yavein and Volkoff have been recognised as *privat-docenten* in Medicine and Dr Tomashovski as *privat-docent* in Neurology and Psychiatry.

Tübingen—Dr Siemerling, Assistant in the Psychiatric clinic in Berlin, has been offered the chair of Mental Diseases, with the Directorship of the Psychiatric clinic. Dr Winteritz has been recognised as *privat-docent* in Gynaecology.

Vienna—Drs Hammerschlag and Kovacs have been recognised as *privat-docenten* in Medicine, and Drs R Frank and Gomperz as *privat-docenten* in Surgery and Otolaryngology respectively.

DEATHS OF EMINENT FOREIGN MEDICAL MEN

THE deaths of the following distinguished members of the medical profession abroad have been announced.—Dr Morlot, formerly professor in the Dijon Medical School. Dr G Herbst, Extraordinary Professor of Physiology in the University of Göttingen. Dr A. Boiescu, clinical professor of the diseases of children in the Bucharest School of Medicine. Dr Wm. B Davis, late professor of Materia Medica in the Miami Medical College, Cincinnati. Dr Wm W Dawson, formerly Professor of Surgery in the Medical College of Ohio, Cincinnati.

At a meeting held at 16 Cavendish square on Tuesday, March 7th, it was resolved that a "James Anderson Memorial Prize" be instituted as a memorial of the life and work of the late Dr James Anderson. A committee has been formed consisting of Sir Andrew Clark, Bart. (chairman), Drs Hughlings Jackson, Ferrier, Ormerod, Gilbert Smith, Levers, R. W. Burnet and Gerald Fitzgerald, the two last mentioned gentlemen to whom subscriptions should be sent, to act as secretaries to the London committee. The London committee will coöperate with the committee in Aberdeen to consider the details of the scheme.

DR. CHARTERIS of Glasgow has received an invitation from the Faculty and officers of the Post graduate Medical School and Hospital at Chicago to deliver an address in that institution on a subject allied to general medicine. The invitation comes through Dr Franklin Martin, secretary to the Faculty, who feels himself in a position to guarantee the presence of a large and appreciative audience on the occasion. It is proposed that the lecture should be given some time in September next.

At a meeting of the Medical Society of London, held on March 20th, Dr Robert Barnes was elected an Honorary Fellow on the nomination of the Council.

carbon," however, would tend to reduce the indiscriminate consumption of alcoholic beverages, we should gladly welcome it *vice* that of "brandy [or whisky] and soda" (obsolete)!

THE INTERNATIONAL SANITARY CONFERENCE

As it was agreed that the proceedings of the Congress should be of a private character no report of the discussions has been published. It is satisfactory to learn, however, on the authority of Vice President Herr von Hengelmüller, that the object of the Conference will most probably be secured, viz., an international agreement on such sanitary measures as will give rise to the smallest amount of restrictive regulation compatible with affording reasonable security to the populations concerned. It is to be hoped that one result of the Conference will be to relax, if not to remove altogether, some of the quarantine restrictions and to replace them by the application of such sanitary measures and practical remedies as are dictated by experience and a knowledge of hygiene.

THE COVENTRY PROVIDENT DISPENSARY

AN interesting event has just taken place at Coventry. The Coventry Dispensary has long been known as one of the largest and, in a commercial sense, one of the most prosperous in the country, but, like other similar dispensaries, it has appeared to members of the medical profession to have absorbed a large number of persons who were never meant to be included in the benefits of such institutions. The medical practitioners of Coventry requested the committee to receive a deputation on the subject, and it agreed to do so. The deputation consisted of Dr Milner Moore, Mr C W Iliffe, Dr Halg, Dr Rice, Dr Harman Brown and Mr Irving Day. The spokesmen were Dr Moore and Mr Iliffe, and they stated the abuses of the provident dispensary system with great moderation and care, showing that a system devised for the benefit of the wage earning classes had been turned to the uses of all classes. The consequence was that the better classes of patients, receiving attendance for very inadequate payments, were apt to receive more attention than others. Mr Iliffe said the better to do classes had availed themselves of the opportunity of obtaining cheap medical attendance, and the thing had become a gigantic commercial enterprise. More than half the population utilised the Dispensary. The method of paying a commission to a collector and giving him a free hand was the main cause of the disproportion between the poorer classes and the well to do. He thought the aggregation of so many in waiting rooms for a length of time must also be dangerous where infectious diseases had to be dealt with. The deputation suggested a wage limit of £2 earned by a man and his family. The members of the committee listened with attention, but they did not seem to agree with the main suggestion, arguing that £2 per week represented very different means, according to the size of the family, its healthiness &c. The conference may yet do good. It was conceived in a spirit of reasonableness, and the committee will be well advised in carefully considering the complaints and suggestions made.

RECENT PREVALENCE OF FEVER

It is gratifying to be able to report that the incidence of scarlet fever shows a definite decline. About a thousand cases were notified in the chief towns of England and Wales during the week ended March 18th, a diminution of close upon a hundred. Manchester, West Ham, Cardiff, Swansea and Birmingham contributed the most, next to London, which had less than a third of the total number of cases. The incidence of diphtheria was about the same—viz., 300, of which the metropolis furnished more than half, Cardiff coming next. London, on the other hand, showed a lesser incidence of enteric fever—viz., a fifth of the whole, Birmingham being next in order. During the same time 30 deaths occurred

in London from scarlet fever, 65 from diphtheria and only 5 from enteric fever. The London scarlet fever mortality was above the weekly average by 13, but there were fewer hospital admissions of that disease and fewer remain under treatment. Though not so many cases of diphtheria were admitted, the numbers under treatment remain about the same and the mortality has been the highest on record. The cause of this persistent prevalence of diphtheria in London and its serious fatality deserve the fullest inquiry. We learn that at Bristol and Grimsby the sanitary authorities are instituting prosecutions for illegal exposure of articles and persons infected with scarlet fever. This disease, as well as enteric fever and measles, is reported to be very prevalent in the Rhondda Valley of Wales. A mild but extensive epidemic of measles is prevailing, also, at Tadcaster, involving some 200 cases and causing the Board schools to be closed. The malady is raging at Brynamman, near Cardiff, and Downfield, near Dundee. This Scotch town does not seem able to get rid of its typhus fever, cases still occurring weekly. An alarming outbreak of puerperal fever, involving, it is said, 50 cases and 14 deaths, is reported from the Ogmore and Garw valleys of Mid Glamorgan. Scarlet fever is said to be endemic in these valleys and the drainage and sewerage are reported to be highly faulty. Many of the cases, however, have been traced to direct infection. The county council is making inquiry into the matter.

SMALL-POX IN THE PROVINCES

DURING the past fortnight there has been neither any very marked increase nor any notable abatement in the number of cases of small pox notified in the various districts of the country, and there have been few fresh districts invaded by the disease. Excepting the southern and western counties, the disease is now prevalent in the whole of England—in many parts, however, limited to a single case—whilst in others, where it has prevailed for months past, it still continues to recur with regularity in spite of the efforts of the sanitary authorities. In respect to the latter we note with regret that the question of hospital accommodation was shelved at a recent meeting of the Aberdovey Board of Guardians, although several cases have occurred in Hereford and the neighbouring counties. *Per contra*, there is much activity in South Wales to meet any emergencies which may arise, and it seems to be recognised that the best economy is that which finds a place prepared with means for the prompt isolation of patients. In the northern counties the disease is still very prevalent, and it may be noted that the Keighley district is becoming more and more a centre for the disease, which still persists at Bradford, Leeds and in many other parts of the West Riding. This long continued prevalence in a district once invaded is in accord with former experience, and it should impart caution to those who predicted a speedy termination to the outbreak at Leicester. The abatement in that borough during the past week or two must not be taken as indicating a cessation of the epidemic there. Not long ago a prominent anti-vaccinationist at Leicester actually attributed the mildness of the present outbreak when contrasted with that of 1871 to the fact that the proportion of unvaccinated to vaccinated children has been practically reversed. How far he was justified in his contention may be gathered from the fact that up to March 28th there had been 140 cases—83 adults and 57 children—with 10 deaths—2 adults and 8 children. These 8 children were unvaccinated, and the two fatal cases in adults were—one in a person who presented a single first vaccination mark and the other in a patient who had no visible mark at all. Of the 140 cases, 83 were adults, of whom 77 were vaccinated and 6 unvaccinated. The

warm blowing to the south westward.' We have here on the Lakes authority the statement that the Scilly Isles is the warmest spot in England, and with it the explanation, for Scilly is the most south west part of England.

What are the climatic features which are necessary to constitute a claim to any place being considered a 'winter health resort' 1. Mildness and equability of temperature. A place must not only be mild, but it must also vary but little from day to day, the extremes must not be great. 2. Abundance of sunshine with a moderate rainfall, so that opportunities of open air exercise are frequent. 3. Pure air, free from dust particles and organic impurities. 4. Absence of prolonged and high winds. 5. A light and porous soil, easily drained and warm. These five points are considered to be the most important and practically include all that is necessary to be taken into consideration. How far, then, do the Scilly Isles fulfil these conditions?

1. *Mildness and equability of temperature*—I have no hesitation in stating that the temperature of these islands is the least variable of any place in the United Kingdom. The following statistics are evidence of the truth of my statement. The mean temperature for the whole year is 52.1, the mean temperature for the winter months—i.e., from November to April inclusive—is 47.05, the mean range for the whole year is 15.1°, the mean range for the winter months is 3.7°. These figures are calculated from observations extending over the twenty years 1871-90. The absolute maxima throughout the twelve months in the year 1881, which is an extreme example, ranged between 54 and 70, and the absolute minima between 29 and 52, the monthly range being 21.3°. These latter data of extremes are taken from another source than the daily Weather Report and I cannot touch for their strict accuracy, but they are certainly to be approximately true at least. It is frequently objected that statistics and figures may be so manipulated as to apparently prove almost anything according to the prejudice of the individual dealing with them. Perhaps that is so and it is certain that the best intentioned may make mistakes in working out statistics, but I shall now adduce evidence of another kind which will be strongly confirmatory of there being but trifling error in the above figures. Tropical, not to mention subtropical, plants will grow in the open air only where they are not exposed to very low or great vicissitudes of temperature. Here is a short list of such exotics grown in these Islands, and more particularly in the Abbey Gardens at Treco—*Anopterus glandulosus*, of Van Diemen's Land; *Cornus virens*—*C. cardinalis* and *C. alba*, of New South Wales; *Arancara Biarvilli*—*A. Cookii* and *A. excelsa*, of More on Bar Norfolk Island; *Abutilon vitifolium*, of Chili; *Aloe scottiana*—*A. karbadoensis* and *A. spicata*, also very many other varieties, from the Cape of Good Hope; *Davallia zerotrichum*, of Mexico; *Dracena Draco* of the East Indies and Teneriffe; *Puya langhinosa*, of South America; and *Cassia corymbosa*, of Buenos Ayres. This list might be very greatly extended by the enumeration of many other specimens of exotic flora. Over fifty species of *Meibomia* and *Meibomia* clothe the rocks of Scilly and eucalypti and bamboo grow well. There seems to be no possibility of doubting or disputing the positive proof which the growth of luxuriant growth, too not mere existence—of these exotics furnishes of the mildness and equability of the climate of the Scilly Isles. They are unimpeachable evidence of the practical accuracy of the statistics brought forward. The means and means of taking meteorological observations are liable to error for it has been pointed out that the surface temperature of the ground is often from five to ten degrees lower than that indicated in the minimum thermometer in ordinary use. As the plants in and passing through the ground will feel and have to contend with the real temperature, their very existence is the best test of temperature, and in the case of Scilly at least is strong presumptive evidence, as I have already said, that the thermometrical readings and the surface temperature correspond very closely.

2. *Abundance of sunshine and slight rainfall*—I am verily heartily handicapped here, for I have to confess at the outset that, with regard to sunshine, I have no statistics to offer. There is no sunshine recorder in this station. Why the Meteorological Office has neglected to supply so important an instrument as the heliograph to these islands I cannot say. If an oversight, it is a deplorable one and ought to, as I hope it will, be remedied very soon. The instrument is not very expensive or very difficult to manage. The value of such observations cannot be exaggerated and their

absence can but be regretted. One's own impressions and the impressions of others are not reliable and certainly are incapable of being reduced to figures. I believe firmly that these islands would compare very favourably with most places as regards sunshine in the British Islands, but in the absence of corroborative evidence my opinion must be taken for what each may consider it worth. I might perhaps proceed to argue that, because the rainfall, as I shall show immediately, is small as compared with other places in the South West, therefore the probabilities are that sunshine is abundant unfortunately, however, there are other causes in operation besides rain clouds to prevent the sun from shining—such, for example, as fog. Negative evidence is at the best but of small value, so I think it better to bow to the inevitable and pass on to the consideration of the rainfall. The average for the year is 34.38 in. This is the result of observations extending over twenty years. Probably the principal reason for this very moderate rainfall as compared with other places on the south west and west coasts is the fact that the land lies low and offers no obstruction to the passing clouds. One point of interest and importance in connexion with the rainfall here is that it is rare for rain to fall continuously for the twenty four hours. Still more uncommon is it for rain to fall continuously for two or three days on end, as a matter of fact, I do not know of any record to that effect. More common—indeed the rule—is it for the rain to fall during the night and for the day to be fine, or the morning may be wet and the afternoon fine, or vice versa. The days on which even young children require to be confined to the house on account of rain are few and far between. I may at once say that there are very few days throughout the year in which the youngest, oldest or most delicate person may not enjoy some time in the open air. Associated with rainfall, and perhaps more important than it even, is the hygrometrical condition of the atmosphere. The mean temperature of the dry bulb thermometer for the year is 52.3 and of the wet bulb 50.3. The mean relative humidity therefore, according to Glaisher's table, is 85 per cent. This is high as compared with many places. It is above the amount or percentage of humidity which is considered most agreeable to health by people, but on the other hand more agreeable to those suffering from chronic respiratory affections. To this also in very great measure is to be ascribed the equability of the temperature the cool summer, and the mild winter. Again, to this same cause is due the fact that the daytime is less warm in summer and the night less cool in winter. There are disadvantages however attending this high degree of relative humidity. Should the temperature fall to any extent the change is felt more keenly than if the atmosphere were drier. It may be noted, too, that people coming from inland districts old people and very delicate persons are very ready to think that the thermometer must be at fault when the wind rises, the sensation of coolness from this same cause being greater than in reality, but after a short time they become accustomed to it and cease to feel any discomfort from slight changes.

3. *Pure air*—The geographical position of the islands and the absence of public works and manufactures are sufficient guarantees of the purity of the atmosphere. The Scilly Isles are the most advanced outpost in the Atlantic Ocean of Great Britain. Then if it be true, as is generally stated and believed that the ocean atmosphere is more highly charged with ozone than that over continents the islands must enjoy a large abundance of this most valuable and best of disinfectants. Indeed, to this and to the fact that the islands are fully exposed to every breeze that blows may be ascribed the comparative immunity of the inhabitants from many of the diseases so prevalent on the mainland. There are no stagnant places on the islands, the air is constantly being changed, as seldom or never is it perfectly calm. As might be expected, saline particles, in greater or less amount, are of frequent occurrence in the atmosphere, and are no disadvantage, but on the contrary may be considered beneficial. Life on the islands is quite comparable to life on board ship but with none of its attendant disadvantages, so free is the exposure and so perfectly pure the air.

4. *Absence of prolonged and high winds*—Here should be added the words, 'either very cold or very hot,' for it is inconceivable that the wind itself, even if it be high, can be prejudicial, provided always the temperature is comparatively mild. It is seldom or never perfectly calm in Scilly, there is generally a breeze and frequently a fresh breeze. Gales, too, are not uncommon—that is, comparatively speak-

THE *précis* of the London Post-graduate Course of vacation lectures and demonstrations to be given daily at King's College between April 17th and 28th is very full, and will include lectures and practical work in various branches of bacteriology by Professor Crookshank. The lectures will deal with the following subjects: The microscope, cultivation of bacteria, examination of air, soil and water, anthrax and malignant oedema, tuberculosis, leprosy and glanders, actinomycosis, typhoid fever and diphtheria, erysipelas and suppuration, tetanus, rabies and cholera. At the Parkes Museum Professor Wynter Blyth and Dr Sykes will give lectures and demonstrations on alternate days on subjects connected with hygiene and public health. Here, again, the programme will be very full and varied, and will deal with points of great interest and importance.

DR. FEDOROFF, of Moscow, publishes in the March number of the *Zeitschrift für Hygiene* some experiments made by him during last summer in the treatment of cholera by means of subcutaneous injections of a fluid prepared by adding cholera bacilli to an extract of thymus gland. The results were so far satisfactory as to justify further experiment.

AT a recent discussion on sewage farms and typhoid fever at the Medical Society of Berlin Professor Virchow expressed the opinion that the sewage farms of Berlin cannot be regarded as in any way tending to spread typhoid fever, and stated that no single case of it had been traced to the drinking of the effluent water.

THE Bucks County Council have agreed, by a majority of only three votes, to establish a sanitary committee. The numbers voting were twenty one for, and eighteen against, the motion.

ROYAL COLLEGE OF PHYSICIANS OF LONDON

ELECTION OF PRESIDENT

AN extraordinary meeting of the Comitia was held on March 27th, at which the principal business was the election of a President for the ensuing year. Sir Andrew Clark obtained 104 votes in a Comitia of about 120 Fellows, and was consequently elected for the sixth year in succession. A few votes were divided amongst Sir Richard Quain, Dr Wilks, Dr Russell Reynolds, Sir Dyce Duckworth, Sir Joseph Fayrer, Dr Broadbent and Dr Playfair. Licences were granted to Messrs G. H. Longton and C. A. Hill, and a communication from the War Office to the College in reference to the constitution of a Board of Examiners for the British and Indian Medical Services was read, the Secretary for War explaining that, whilst he could not accept the scheme suggested by the Royal College of Physicians, he would in future select examiners from the Conjoint Board of England for a period of four years each. A Member was granted permission to resign his Membership. The Rector of the University of Padua thanked the College for sending a representative to the Galileo Tercentenary, and Sir Joseph Fayrer presented to the library the books and photographs which had been presented to him as the delegate at the celebration. The Rector stated that there were two armorial bearings of Harvey at Padua, and he would send photographs of them to the College as soon as they were restored. The President then delivered his address, which dealt with the more important matters affecting the history of the College during the past year. After referring to some letters concerning the policy of the College, its numbers and the expense of keeping up the fabric, he pointed out the necessity, in order to provide for the comfort of the lecturers and the audiences, of a new lecture theatre, but said that the

finances of the College did not at present warrant even the necessary outlay for such an important improvement. The finances of the College were undergoing a severe strain in maintaining the research laboratories on the Embankment and it was suggested that a special finance committee should be appointed for dealing with the expenditure of the examination building. The Censors' Board had considered more cases of the giving of laudatory testimonials by members of the corporation than in previous years. The lawsuit with the General Medical Council as to whether the Licentiate was a complete qualification was the most important event in the history of the College for the year, and it was satisfactory to find that the verdict had been given in favour of the College, with costs. The registrar, Dr E. Liveing, was especially to be thanked for his arduous work in connexion with this case. The President, the Registrar, and Drs Norman Moore and Allchin gave evidence before the Gresham University Commission in July last. Sir Andrew Clark then referred to the deaths of Fellows in the past year, and detailed the most important points in the medical history of Drs Walshe, Gueneau de Mussy, James Ross and James Anderson. He dwelt most sympathetically and eloquently on the careers of these physicians and it was a subject of regret that time did not permit him to refer to the other deceased Fellows. On the motion of Sir Henry Pitman it was unanimously resolved that the President's address should be printed, to which Sir Andrew Clark assented.

THE ISLES OF SCILLY AS A HEALTH RESORT

CLIMATOLOGICAL NOTES

BY T. THORNTON MACKLIN, M.B., L.F.P.S. GLAS,
D.P.H. CAMB.,

FELLOW OF THE ROYAL SCOTTISH GEOGRAPHICAL SOCIETY ETC.

VERY little is known of the Scilly Isles by the general public, and I am safe in saying that still less is known of their very exceptional climate by medical men. In recent years, it is true, a considerable amount of attention has been called to them in the lay press by several writers, but I am not aware of any article concerning them—save that by Professor Charteris of Glasgow, which appeared in *THE LANCET* of Nov. 18th 1890—having appeared in any medical journal. Having been resident for nearly two years in the islands I desire to make known something of their rare climatic qualities. Much interesting and general information concerning their natural beauty and picturesque scenery will be found in that charming book by Walter Besant, "Armored of Lyonesse." Shorter and more generally descriptive articles have appeared in various magazines and the daily papers, and to these I must refer any who wish to learn more than I purpose to deal with here. My object is to furnish such meteorological data and to point out such climatic features as will go a great way in demonstrating the claim the islands have to be considered a "winter health resort." Mr R. H. Scott, secretary to the Meteorological Office, in a recent article in *Longman's Magazine*, says: "It is a very difficult thing to find trustworthy data as to the climate of health resorts. In the first place, there are comparatively few of these at which regular observations are taken, in the second, the residents of each place are in the habit of vaunting the advantages of their own town over all its rivals" &c. These remarks cannot, and do not, apply to the Scilly Isles, for, in the first place, it is one of the meteorological stations where regular observations are recorded, in the second place, it is not yet in competition with other places as a health resort, and no comparison is attempted. My object is to bring it under the notice of my medical brethren and to supply them with as accurate climatic data as can be found. These data may be considered thoroughly reliable, for they are for the most part, taken from the Daily Weather Report issued by the Meteorological Office, and such as are not so derived are capable of demonstration and may be verified by any one who will do himself the service and give himself the pleasure of visiting the islands. Before proceeding further I will make another quotation from the article already cited: "The warmest spot, taking the whole year round, is the Scilly Isles. They are a whole degree warmer than either the west of Cornwall or the Channel Islands. In winter the lines of equal temperature run generally north and south, the

some way the manner in which the heart, which is a self-acting muscle, would stop after the arrest of its nutrition by stoppage of the respiration with poisonous doses of chloroform, and he also pointed out the flaw in the Glasgow Committee's criticism of the Hyderabad Commission which appeared in the *British Medical Journal* of June 14th, 1892. But for Dr Gaskell's encouraging interest and friendly aid the object of my visit to England would have been frustrated.

4 Under these circumstances and impressed with the strongest possible feeling of obligation to Professors Foster and Gaskell I considered myself justified in requesting Dr Gaskell to undertake a critical examination of the tracings of the Hyderabad experiments and to make any additional experiments he deemed fit. I believed that Dr Gaskell and Dr Shore's work would support and amplify the conclusions of the Commission and, disappointing though at first sight the report is, I still retain this opinion in a modified form.

5 With regard to this point I cannot do better than quote the words of Sir Asman Jah, in the preface to the Report of the Hyderabad Commission: "I agree in the view that free criticism and discussion are essential to the final acceptance of the principles brought forward by the Commission." Dr Gaskell's criticism of the Commission's work was invited by His Highness's Government and his independent and unfettered inquiry has unquestionably furthered the end that Government had in view.

6 It is clear from a careful perusal of their report that Drs Gaskell and Shore are saturated with the prevailing notions of the action of chloroform on the heart. In this way their conclusions have been biased throughout and they have evidently interpreted everything in their experiments that could be thought to show such action as a proof of the prevailing belief. This attitude of mind has been confirmed by the results of their cross-circulation experiments.

7 Cross-circulation experiments are new to this particular research, and there can be no question that in their case Drs Gaskell and Shore have argued from an insufficient number of experiments of an excessively complicated character. Following Dr Gaskell's lead I have repeated these most interesting and important experiments in a considerably large number of cases, as it is only possible to do at Hyderabad.

8 The result of our cross-circulation experiments is that we have been able to place the proofs that chloroform does not directly affect the heart on a surer basis than ever Dr Gaskell's and Dr Shore's report has consequently led indirectly, to results of the most important and far-reaching kind.

9 Finally Dr Gaskell's and Shore's practical conclusion, that "chloroform can be given with perfect safety," is in itself the most valuable of all proofs of the enormous influence for good that has resulted from the Hyderabad Commission. It is not too much to assert that such an opinion would never have been arrived at, much less published prior to the work of that Commission.

10 I would venture to suggest that the cordial and hearty thanks of His Highness the Nizam's Government be tendered to Professor Gaskell and Dr Shore together with the intimation that should they ever feel inclined to repeat their experiments on a more extensive scale, in order to bring them into line with those carried out in Hyderabad, Government will provide the necessary funds to enable them to do so.

I have the honour to be Sir your most obedient servant,
(Signed)

E. LAWRIE, Surgeon Lieutenant-Colonel, Residency Surgeon.

(True copy)

E. LAWRIE, Surgeon Lieutenant-Colonel.

Together with the above copy of the correspondence on Drs Gaskell and Shore's report, we have received the following memorandum from Surgeon Lieutenant-Colonel Lawrie addressed to us with a request for publication in THE LANCET—

1. If Dr Gaskell's and Dr Shore's experiments could be proved to be decisive, the contention and findings of the Hyderabad Commission would necessarily fall to the ground. On this possibility we join issue. We have performed numerous cross-circulation experiments since September, 1892, and it is so certain as to be beyond dispute that when the cross-circulation is successfully established and maintained, and chloroform is sent to the brain alone, the same sequence of events is observed as when it is inhaled in the ordinary way. On the other hand, when chloroform is sent to the heart alone, and has no access to the brain, it produces no effect whatever, nor can any effect be produced on the system by chloroform except through the brain. So completely is the action of the anæsthetic limited to the brain that, after a little experience had been gained in our experiments, the efficiency of the cross-circulation could be estimated with precision by its effect on the fed animal, but we were not content with this, and in all the later experiments results were verified by post-mortem injection and examination of the bloodvessels of the animals' brains.

2. The self-evident fallacy in Drs Gaskell and Shore's experiments is that the cross-circulation was not maintained, or, in other words, the "fed's" brain circulation was incompletely blocked, and blood was conveyed to it from its own system through collateral channels. Conclusive evidence on this point is furnished in Figures 9 and 10 p 169 of the *British Medical Journal* of Jan 28th, 1893. These are tracings of two cross-circulation experiments on two pairs of rabbits in which chloroform was administered to the "fed." The drug was to have no access to the "fed's" brain, which was to be supplied with unchloroformed blood from the "feeder," and yet in both experiments the "fed's" brain died of chloroform

poisoning. The chloroform must have been conveyed to the nerve centres by the collateral circulation, as failure of the "fed's" heart could not have killed its brain if the cross-circulation had been effective and its supply of pure blood from the "feeder" had been maintained throughout the experiment.

3 The danger of the belief that chloroform directly affects the heart lies in the risk of the perpetuation, no matter in what form, of the teaching of the Glasgow Committee of 1879, which established the pulse as a factor in chloroform administration on a pseudo-scientific basis.

4 In 1879 the Glasgow Committee of the British Medical Association published manometer tracings exhibiting sudden falls of the blood pressure under chloroform, which were accepted and acted upon by the majority of the profession as signs of impending death from direct stoppage of the heart. In 1892 Drs Gaskell and Shore put forward manometer tracings exhibiting gradual falls of the blood pressure in experiments with chloroform, which they are firmly, though I hope not unalterably, convinced indicate danger owing to direct weakening of the heart.

5 If Dr Gaskell's and Dr Shore's dictum were true that "the weakening effect of chloroform on the heart is the chief if not the only cause of the fall of blood pressure," it would obviously be necessary to watch the pulse during chloroform administration, and even with this precaution it could not be administered with invariable safety. The principles upon which, following Syme, I and hundreds of his pupils all over the world have given chloroform with success are that it is useless and unsafe to take the pulse as a guide and that uniform safety can only be assured by entirely disregarding the heart as a factor in the inhalation of the anæsthetic. The Hyderabad Commission has verified Syme's teaching and has proved that neither the sudden falls of the blood pressure of the Glasgow Committee nor the gradual falls on which Dr Gaskell and Dr Shore lay stress are in themselves dangerous or afford any reason for taking the pulse as a guide, and our cross-circulation experiments have completed the Commission's work by demonstrating that chloroform has no direct action on the heart. Falls of the blood pressure under chloroform are accordingly of no consequence unless the heart is weakened by interference with the breathing and is thus made to take part in their production. It is abundantly clear therefore that the pulse can only afford useful indications to the chloroformist when chloroform is administered in such a manner as to interfere with the respiration.

6 It would be interesting to differentiate between the falls of the blood pressure due to the various causes which are at work in over dosing with chloroform, so as to be able to state exactly where the harmless fall caused by vaso-motor narcosis ends and the dangerous fall due to weakening of the heart from failure of the respiration begins. In the laboratory this is impracticable in the present state of our knowledge and appliances, whilst in the operating theatre it is a point of no practical importance whatsoever. Clinically the heart is never affected under chloroform at all if the breathing is natural and regular throughout the administration.

E. LAWRIE, Surgeon Lt Colonel, Residency Surgeon.

CHOLERA IN FRANCE

(FROM OUR SPECIAL CORRESPONDENT)

A VISIT TO MARSEILLES

Endemic Cholera—The High Death rate—Contaminated Cisterns—Draining into the Gutter

THE general insanitary condition of Marseilles is not only such as to account for the occasional outbreak of cholera and other epidemic diseases but there would be nothing to be surprised at if cholera were to become endemic. Indeed, it is an open question whether cholera is not actually endemic at Marseilles. There were the two great epidemics of 1884 and 1885. But in 1889 several medical men who were about to attend the International Congress of Hygiene held at Paris during the Universal Exhibition were detained at Marseilles because they thought an epidemic of cholera was about to break out. There is an especially unhealthy house where the first cases of cholera occurred in 1885, and in 1889 there were three cases of cholera in this one house just at the time that the

ing Scilly lies within the south west district of the Meteorological Office and it is the one "most frequently swept by gales, the average being twenty two per annum." Gales from the south west preponderate very considerably over those from other quarters, and then, of course, the weather is very mild. The worst wind in these islands is from the north west and it has a shrivelling up effect if it blows strongly. There has not, however, been such a gale within my experience and they occur very infrequently. The east wind is cold, of course, but still it is tempered to some small extent by the miles of water which it has to pass over before reaching the islands. In sheltered places where one is protected from the wind the sensation of warmth is so great that one can lounge about and even sit down for a time without any sense of coldness or discomfort. Indeed, so pleasant and mild is the atmosphere when in shelter that one can hardly credit the wind to be blowing from the east. Regarding shelter from any wind, however, there is not very much to be said. The natural configuration of the islands is such that shelter is not easily obtained except in very small patches. There are no high hills and no belts of timber to afford protection from the wind from whatever quarter it may blow. On the whole, then, this is the weakest point in the claim of the islands to be considered a "winter health resort" if absence of strong winds or shelter from the same is to be considered absolutely necessary.

Fortunately, however, for seafarers generally and the inhabitants of these islands in particular, it is not always, or even commonly, blowing a gale of wind, and, besides, very often gales occur during the night when most people are safely in bed, where invalids and health seekers would most certainly be, and therefore not exposed. Individually, I am not quite so sure of the supposed great advantage of a still atmosphere for invalids and health seekers. I am quite prepared to contend that fresh breezes and even strong winds occasionally, are decidedly beneficial as they are more exhilarating and invigorating than a calm, still atmosphere.

5 *A light and porous soil easily drained and warmed*—In this respect I consider that the islands are almost perfect, the rocks are granite, and the soil is light, loose, sandy and porous, the natural drainage being excellent. The ground is undulating and on the slopes the rain disappears at once, but even on the low lying and level places the water is found to lie for a very short time. After the heaviest rainfall, in a comparatively short space of time the most delicate need have little hesitation in walking abroad. The gravels and the sands are generally recognised to be the driest and the healthiest, being the most porous soil. That the soil is also warm has already been demonstrated when reference was made to the marvellous vegetation of the islands.

It is in these islands that the narcissus culture is so extensively carried on, and whence the large cities derive so large a part of their winter and spring supply of flowers. Lilies blooming in the open air in January, even at Christmas time occasionally, are not found in many places in England, if, indeed, in any, nor for that matter on the Continent either. I think it is clearly established that the Scilly Isles enjoy a remarkably mild and equable climate not to be excelled, if at all approached, by any other place in England, that the rainfall is extremely moderate and occurring under most favourable conditions, that the air is pure and uncontaminated by deleterious matter, and that the soil is of the kind considered healthiest, being dry and easily drained. The want of exact information regarding the amount of sun shine is unfortunate and can be remedied only by time.

Then as regards the prevalence of fresh breezes and general want of shelter in the islands, such patients as would be injuriously affected thereby would avoid the place as being unsuitable to them. The natural advantages of the place are very great and the climate is peculiarly suitable for a certain class of invalids and delicate people, and more especially for those with a tendency to phthisis or suffering from the disease in its early stages. Strumous cases also, and nearly all 'chronic respiratory complaints are almost certain to be much benefited. The islands are within less than eighteen hours' journey of London, consequently very near to and within easy reach of every English home. The steamboat communication is fairly good, but might easily be much improved. Unfortunately there is at present a lack of good accommodation for visitors, though lately a few good houses have been erected. The houses are for the most part small and badly situated, no one, in building, having apparently had any idea of obtaining a view. It re-

quires only a little enterprise on the part of the inhabitants to make very great improvements and augment the favours which nature has already lavished so abundantly on these islands. A place where snow seldom falls, or if so very scantily and soon disappearing, and where frost and ice are hardly known, may, I think, with some justice fairly lay claim to being considered a "winter health resort" to which the delicate and the invalid may repair with every hope of being benefited, and in many cases even of being restored to health. At some future date I may enter more into detail on some points already touched upon and give some account of cases which have been benefited by a residence here. The vital statistics of the islands, too, are not without interest for in a community numbering less than 1800 souls the number of people who have attained to a great age is, I believe, much above the average.

THE HYDERABAD CHLOROFORM COMMISSION

To the Editors of THE LANCET

SIRS,—I beg you will do me the favour of publishing the enclosed correspondence and memo on the report of Drs. Gaskell and Shore.

THE LANCET of Feb 18th, 1893, which arrived here to-day, contains a letter by Dr Gaskell and Dr Shore regarding the publication of their report. From it I gather that there has been a misunderstanding on the subject, which I much regret. The report was forwarded to us without any intimation that it was a draft, and, as from its nature there was no reason to believe it to be such, we never regarded it in that light. Accordingly, as it was a piece of private work for His Highness the Nizam's Government, we were under the impression that it was ours to do what we liked with. We originally intended to publish it in the medical journals, with a detailed reply, and we should in that case, in fairness to Dr Gaskell and Dr Shore, have submitted it to them, together with the report, before publication. Subsequently, however, the results of our cross circulation experiments rendered this procedure unnecessary, and the report was therefore forwarded to Government for publication in due course in the annual administration report. In the meantime Drs Gaskell and Shore have published the report themselves. In view of these facts it is somewhat extravagant of them to accuse me of an intention of suppressing their investigation. We now know the whole truth about chloroform, and we give Dr Gaskell and Dr Shore full and entire credit for the part they have taken in enabling us and the medical world to arrive at it. I am, Sirs, yours truly,

Deccan, March 7th, 1893

EDWARD LAWRIE.

Private Secretary's Office Feb 22nd, 1893.

From Faridoonji Jamsheji Esq

Private Secretary to H E the Minister,
To Surgeon Lieutenant-Colonel E. Lawrie, M.B.

Residency Surgeon, Hyderabad.

SIR—I have the honour to acknowledge the receipt of the Report of Chloroform by Dr Gaskell and Dr Shore.

2. It is evident to Sir Asam Jah as it must be to the most careful reader, that this Report is opposed to the conclusions of the Hyderabad Commission from their very foundation and is not a finishing touch to the Commission's work as it was intended to be.

3. I am directed therefore to request that you will furnish His Excellency with an explanation of this fact.

I have the honour to be Sir your most obedient servant
(Signed) FARIDDOONJI JAMSHEDJI Private Secretary

(True copy)
E. LAWRIE, Surgeon Lieutenant-Colonel.

No 11 of 1893

From Surgeon Lieutenant-Colonel E. Lawrie,
Residency Surgeon Hyderabad,

To Faridoonji Jamsheji Esq

Private Secretary to His Excellency the Minister

Dated Hyderabad Residency March 6th 1893.

SIR—I have to acknowledge your letter of Feb 22nd 1893 directing me to submit an explanation of the fact that the Report on Chloroform of Drs Gaskell and Shore is opposed to the conclusions of the Hyderabad Commission from their very foundation and is not merely the last finish to the Commission's work as it was intended to be.

2. In reply I have the honour to remind you that when I proceeded to Europe in 1890 I endeavoured to obtain with the sanction of His Highness the Nizam's Government the help of the most eminent physiologists in England to complete the work of the Hyderabad Commission.

3. Acting on the advice of Sir Joseph Lister I visited Cambridge with Dr Lauder Brunton and laid the Commission's tracings before Professors Michael Foster and Gaskell. They were struck with the fact brought out by the whole of the tracings that chloroform lowers the blood pressure and this appeared to them to indicate danger to the heart. On the other hand, Dr Gaskell explained to me, in a common

tion of the luggage of healthy passengers is equally condemned. The process of disinfection (so-called), as carried out this winter on the German side of the Russo German frontier, led to much annoyance and could by no possibility have kept out the cholera (or any other) bacillus. The report insists on the necessity of supervision on the lines of communication where large bodies of passengers are concerned, such as labourers, troops, emigrants and convicts, and also of providing them with cheap or free refreshments, with shelter and with cheap baths. With regard to the holding of fairs, pilgrimages and bazaars, the Conference decided that it is quite unnecessary to forbid them or to close places of entertainment during an epidemic of cholera. "The experience of the last epidemic," the report states, "has shown that the danger arising from the congregation of large numbers of people may be reduced to nil by carefully considered measures of precaution."

Means of disinfection.—The necessity of laying in supplies of disinfectants before the spring is pointed out. The use of crude carbolic acid, unless after a thorough analysis is condemned. The crystalline acid should be substituted for it. The methods of disinfection detailed in the Government Circular on this subject have proved satisfactory and call for no alteration or amendment. Finally, the report declares that the attempt to disinfect large packages of goods by simply disinfecting their outer surface or wrappers is of no use.

The members of the Conference were unanimous in the opinion that there are no specific means of curing cholera, and of cutting short its course. An *ex cathedra* statement approving of any one drug or line of treatment was therefore thought inadvisable. The report simply recommends a rational symptomatic treatment, caring being taken that the form of treatment is not wrongly interpreted by the peasantry. The Conference approved of the so-called "cholera medicine cases" in the hands of quacks and others living amongst the peasants as being of use or first aid treatment.

NON-POISONOUS WHITE LEAD

THE highly deleterious properties of carbonate of lead (white lead) on the health of the operatives engaged in its manufacture and of those using it for trade purposes have long been recognised. This has recently been emphasised by Mr Oliver of Newcastle in the Goulstonian Lectures of 1891. The matter has also received attention in the reports of coroners inquests on deaths from plumbism occurring amongst these persons. The recognition of this danger has led to many attempts to minimise it, as it occurs in the process of manufacture, by endeavouring to find a substitute for the poisonous carbonate which should be innocuous or is hardly worth while to record the various suggestions that have been brought forward, but the most promising is that known as 'Hannay's white lead.' The product, however, is not the carbonate of lead but the sulphate. The process of its manufacture does away with all the handling required for conversion of crude lead into carbonate before it is sent into the market. The white sulphate of lead as prepared by "Hannay's" process does not require such manipulation, whilst the product itself is so far insoluble as to be handled by painters with almost if not complete immunity. The new process is as follows. Best English ore containing about 80 per cent of lead is used, and with the exception of being melted it undergoes no preparation whatever before being sent into the furnaces. These, of which some thirty exist in the works, are ranged in a long line stretching from the shed where the galena is stored. They are solidly built, have special last arrangements to ensure the conversion of all the galena into the innocuous sulphate and by a system of flues are placed in direct communication with the condensers. The reaction taking place in the furnace may be thus represented: $Pb - 2O_2 = PbSO_4$. The lead sulphate so formed enters into the condensers where, coming into contact with a cool

ing jet of water, it is immediately precipitated in a fine white powder on the floor. The sulphate, after it leaves the condensers, is then received into settling tanks. Here a sieve catches any rough sulphate which may have been formed by adhesion to the sides of the condensers. It is then left to settle, the extraneous water being afterwards drawn off. It is next washed in acidified water to remove any impurities, and thereupon pressed. Medical men know well that when such cases of plumbism arise from the use of carbonate of lead the remedial agent employed is sulphuric acid or sulphate of magnesia, which converts the carbonate of lead into a sulphate. This non-poisonous white lead has received the commendation of Sir Henry Roscoe and Professor T. E. Thorpe, and several firms have made use of the new pigment and have expressed their sense of its value by repeating their orders. It appears to be of especial value for marine purposes, as it resists the action of salt water remarkably well. For all ordinary purposes the evidence seems to show that it replaces the poisonous carbonate of lead in every respect. When we reflect on the enormous direct mortality, to say nothing of the indirect evils, consequent on the use of carbonate of lead as a pigment, it is to be most earnestly desired that this new preparation may have an enlightened and unprejudiced trial. If the comparatively innocuous white sulphate of lead can replace entirely or in large measure the poisonous white carbonate of lead an enormous saving of life and suffering will be effected, and so far the evidence is entirely in its favour. Indeed, should it be proved that life and health can be preserved by the manufacture and use of this pigment and that it is equally applicable for trade purposes as the old white lead, Government ought at once to enforce its adoption.

At our request specimens of the galena from which this new white lead is obtained and the dry product, as well as that mixed with oil ready for use have been submitted to us for examination. Sulphate of lead formed the basis of both the white lead specimens, although traces of oxide—so small as to be quite negligible—occurred in the dry sample. Treated with weak acetic acid, for instance, it yielded a solution which, on filtering became distinctly turbid on treatment with sulphuric acid. Compared with a very well made specimen of white lead as it is used at present, the new compound is, as might be expected, not so exquisitely fine, although it was certainly much finer, when viewed under the microscope, than we expected to find. As the covering power of a pigment depends on the degree of fineness of the material, it may be supposed that the new preparation is in this respect therefore somewhat inferior to the finest white carbonate of lead, but doubtless it is equal and even superior to many kinds of white lead frequently met with in shops. The covering properties of white lead are dependent in fact upon its condition of aggregation, because a loose crystalline white lead does not cover nearly as well as the perfectly amorphous lead prepared by the old Dutch method. The covering power increases moreover with the amount of hydrated lead oxide. In attempting to find a satisfactory substitute for the old white lead the problem is to find a substance of good weight and bulk and one that is perfectly amorphous and non-crystalline. Sulphate of lead prepared by ordinary methods though beautifully white, is crystalline, and it is this property that militates against its use as a pigment. This difficulty has to some extent been overcome by the method which is adopted by the above company. We have no evidence that it is equal in pigmentary power to the white lead at present in use. Only long experience in its application on a large scale can decide this point, mere experiments in the laboratory are of no value. In the interests of the health of workmen and workwomen who are exposed to the evils arising from the inhalation of lead dust and fumes in the factories where white carbonate of lead is now prepared we should be glad to learn that such experience decides in favour of the new innocuous compound. The new product is cheaper than ordinary white lead, and it resists the destructive action of sulphuretted hydrogen and sea water completely. The deterioration of ordinary lead paint through the presence of sulphur compounds in the air is a matter of common observation in large manufacturing towns, and in the neighbourhood of gasworks the damage from this cause is often serious. In such cases the new material could be substituted with considerable advantage. If this new lead paint were used more freely than ordinary paint for the purpose of coating surfaces doubtless the slight inferiority of its pigmentary power would be counterbalanced.

* The process as witnessed at Eydtkuhnen was carried out by women. The top and sides of each package were wiped over with a damp flannel that had been dipped into some hot fluid. The fluid was laced with dirt. With the same flannel the upper surface of each article contained in the boxes was washed over. Irrespective of its nature woollen clothes, boots and white shirts received the same dirty treatment. The inner surfaces of folded articles were not touched. Linen that had been worn was detained for disinfection by steam.

THE LANCET, Nov. 19th, 1892, p. 1155.

Congress in question met at Paris, and it was thought that this was the beginning of an epidemic. Dr Murreur described to me what seemed to be a true case of cholera which occurred fifteen years ago. Now there has been a small epidemic last October, and another last February. But between these two outbreaks there were isolated cases which there is good ground to suspect were genuine cases of cholera. The question arises whether there are not every year a few deaths from that disease at Marseilles, though the word "cholera" is only employed when instead of a few cases there are a considerable number. A local incident, such as exceptional dryness and the consequent lowering of the underground water level or the more frequent drinking of the cooler well water instead of the less agreeable and warmer town water—or again, as in last February, the falling off through the bakers' strike of the bread supply—may cause the endemic tendency to cholera to develop into a regular epidemic. At any rate, many medical men fail to recognise any well defined difference between the annual cases of what is sometimes called "cholera nostras" and such cases of cholera as occur during an epidemic. The difference seems to rest solely in the number and not in the nature of the cases.

However this may be, there is in Marseilles a semi tropical climate in addition to the worst sanitary conditions, consequently there is not only a special susceptibility to cholera, but a very high death rate, and at times as many as a third of these deaths are due to transmissible diseases. Thus, from 1882 to 1886 there were 60,115 deaths, of which 20,375 might have been prevented. Dr Proust in 1889 estimated the average death rate of Marseilles for the previous twenty years at 32 per 1000 of the population. In some quarters the death rate is much higher and equals, in the Gare du Sud district, 35.0, the Bassin de Carénage, 36.7, the Hôpital Militaire, 37.4, the Arc de-Triomphe, 38.0, the Hôtel Dieu, 38.9, and the Hôtel de Ville, 47.4 per 1000 of the population. There is nothing surprising in this high death rate. Marseilles has an abundant water supply, but the water is polluted before it reaches the town. This, however, might be prevented, and I will leave the general and very important question of the water supply aside for the moment. Dealing at present only with what occurs within the walls of the town, I would protest that even though the water be pure when it reaches the consumer it is very frequently befouled within his house. The water is very generally delivered in cisterns placed near the roofs of the houses. In this position the water becomes still warmer, and, in the hot summer months, this increases the temptation to drink water from wells which, though often polluted, is always cool and fresh. It may be urged that this cannot be helped, what, however, could be prevented is the defective construction of the cisterns. The water usually supplied, that of the aqueduct from the Durance River, is often very muddy, the mud deposits in the cisterns, and the pipes which supply the house have their openings two or three inches above the bottoms of the cisterns. Consequently the deposit is not carried down into the pipes with the water. Unless the cisterns are constantly cleaned out it is better for the mud to be carried down the pipes. Firstly, the thickness of the water would render the use of filters more general, secondly, the mud mixed with the water would be fresh mud. This would not be so dangerous as water which has come off the surface of the stale mud which has been accumulating in the cistern for weeks, months and perhaps years. The mud may be comparatively uninjurious at the moment of its arrival in the cistern, but, in the course of time, it may be polluted, the organic matter it contains will ferment and all manner of evil consequences will result. This is not all if the outlet pipe at the bottom of the cistern is so disposed as to convert the cistern into a mud settling tank, an overflow pipe at the top communicates directly with the house soil pipe and often helps to ventilate not only the household drains but also the public sewers.

There are various methods of draining houses at Marseilles. In the better quarters and for the more recently built houses there are what are called *puisards*—a term badly applied, for, as a rule, a *puisard* means a porous cesspool. In this instance a *puisard* means a small cesspit built under the causeway of the street and in front of the house. This pit may be about three feet square and five to six feet deep. On one side the soil pipe from the house enters it at about two feet above the bottom. On the opposite side a drain pipe communicates with the public sewer, which is a few feet beyond in the centre of the street. The entrance to this drain is protected by an iron grating, so that only liquids and small particles can per-

colate and reach the sewer beyond. The *puisard* therefore retains under the street pavement the solid deposits from each house. A circular iron lid, similar to those seen over coal cellars in London, gives access to this cesspit. Householders pay twenty four francs a year for having the heavy deposits at the bottom of these cesspits cleared away, but this operation is rarely accomplished more than twice a year. Then it often happens that instead of lading out the filth the cesspits contain the men content themselves with throwing water into the cesspits, violently stirring the contents at the same time. The heavy deposits thus diluted are able to flow out into the sewer. Of course, this operation occasions a horrible odour and befouls the sewer, thus defeating the object of the cesspits. It must also be noted that these cesspits do not serve the purpose of dip traps, there is no dip-stone in the centre. The overflow pipe to the sewer faces the soil pipe from the house, the sewer air enters the soil pipe after passing over the foul contents of the cesspit, in the soil pipe the sewer air reaches the overflow pipe from the cistern. Thus the gases, with all the microbes they may contain, reach the surface of the drinking water after travelling from the sewer, from the cesspit, and up the house soil pipe. The purest water might in this manner be befouled, yet this is the method of drainage employed in the best houses and districts of Marseilles. There are from four to five thousand *puisards* under the causeways of the best streets of Marseilles. Some five to six thousand other houses have what are called *tinettes filtrantes*. Under the staircase, in a niche in the wall, or in any other convenient corner, there is a metallic receptacle, the lid of which fixes into the bottom of the soil pipe. At the lower portion of this pit there is a small opening which allows the liquids to flow along a small drain that passes down the entrance passage or hall of the house and empties itself into the street gutter. This is not a pipe drain, but more often like a small gutter, and is sometimes not even covered. In other houses there are what are called dry *tinettes*. Such houses have no closets, but empty their soil into these metallic receptacles, which are generally placed in a small recess under the stairs. Other houses have cesspools, and some few have porous ones that allow all the liquids to escape into the subsoil. These latter are not very numerous. But, worse than all, there are close upon 14,000 houses that have no closets whatever. The inhabitants are forced to make use of public latrines, though the large majority throw every thing into the street gutter. It may be said that, in the main, Marseilles drains into the gutter.

(To be continued.)

THE LATE CONFERENCE ON CHOLERA AT ST PETERSBURG AND INTERIM REPORT

PENDING the publication of the full report of the proceedings of this Conference, the Medical Department of the Ministry of the Interior has issued a statement of the main conclusions at which it has arrived.

Dealing with the measures for improving the health of inhabited localities, the report states that the chief sources of pollution of the soil in Russia are the entire absence or bad construction of *retirades*, and the leakage from cesspools. As the cost of constructing water tight cesspools is great, the Conference recommends the cheaper method of removal of sewage in barrels or in well made and thoroughly tarred wooden receptacles.

The sources of pollution of the water supply are also enumerated. In villages that do not possess wells the construction of "Abyssinian" or other deep wells is advocated. With the object of making a thorough examination of the water supplied to a district possible, the opening of laboratories in all large towns is recommended.

Precautionary measures against the introduction of the epidemic—As has been already stated the principle of quarantine was condemned in no measured terms by the Conference. The present report condemns it as having no scientific basis. For quarantine there should be substituted isolation and disinfection. Further, the inspection of passengers in trains is declared to be useless and irksome, and the compulsory disinfection

ther trial to apply the principle to all impure wells in the tract. We must confess we are not much taken with the amendment, as just the same objections would apply to it as ordinary domestic filters—i.e., the difficulty of ensuring quiet and efficient cleansing.

Loughborough Rural Sanitary District—The total abolition of middens and the replacement of all brick culverters in this district by properly glazed pipes are the two chief recommendations contained in the report. A severe epidemic of measles occurred in the borough during the winter, and the schools were closed in consequence. Mr. Moran made a special report to the authority upon the outbreak, and he endeavours to show, amongst other things, that epidemics of measles have been much more extensive and fatal since the Compulsory Education Act, that school closure reduces the rapidity of the spread of epidemics of measles, although it does not absolutely prevent them. The general death rate of the district was 18·2 per 1000, the infant mortality, decidedly high, amounting to as much as 6 per 1000 registered births.

VITAL STATISTICS

HEALTH OF ENGLISH TOWNS.

In thirty three of the largest English towns 6600 births and 36 deaths were registered during the week ending March 25th. The annual rate of mortality in these towns, which had been 16·6 and 19·9 per 1000 in the preceding two weeks, further rose last week to 20·9. In London the rate was 20·7 per 1000, whilst it averaged 21·0 in the thirty two provincial towns. The lowest rates in these towns were 11·8 in Derby, 15·1 in Warrington, 15·8 in Croydon and in Nottingham, 15·9 in Brighton and 16·1 in Swansea, the highest rates were 25·0 in Leeds, 27·7 in Manchester, 26·7 in Bolton, 26·9 in Salford and 27·4 in Liverpool. The 4136 deaths included 423 which were referred to the principal zymotic diseases, against 350 and 406 in the preceding two weeks, of these, 121 resulted from whooping cough, 102 from measles, 70 from diphtheria, 47 from diarrhoea, 41 from scarlet fever, 28 from "fever" (principally typhoid) and 14 from small pox. No fatal case of any of these diseases occurred last week in Wolverhampton, in the other towns they caused the lowest death rates in Warrington, Brighton and Swansea, and the highest rates in Portsmouth, Leeds, Cardiff, Preston and Bolton. The greatest mortality from measles occurred in Cardiff, Gateshead, Hull, Newcastle-upon Tyne, Portsmouth, Preston, Leeds and Bolton, from scarlet fever in Huddersfield, from whooping cough in Birkenhead, Birmingham and Worcester, and from "fever" in Bolton. The 70 deaths from diphtheria included 49 in London, 7 in Cardiff, 3 in West Ham and 2 in Croydon. Six fatal cases of small pox were registered in London, 2 in Manchester, 1 in Halifax and 1 each in West Ham, Oldham, Leeds and Hull, but not one in any other of the thirty three towns, 23 cases of this disease were under treatment in the Metropolitan Asylum Hospitals and 12 in the Highgate Small pox Hospital on Saturday last. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 1971 against 210, 2147 and 1965 on the preceding three Saturdays, 25 new cases were admitted during the week, against 195 and 180 in the previous two weeks. The deaths referred to diseases of the respiratory organs in London, which had declined from 427 to 338 in the preceding four weeks, rose again to 393 last week, but were 112 below the corrected average. The causes of 87 or 21 per cent., of the deaths in the thirty three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Bolton, Sunderland, Newcastle-upon Tyne and in six other smaller towns, the largest proportions of uncertified deaths were registered in West Ham, Blackburn, Preston and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had declined from 23·2 to 21·2 per 1000 in the preceding three weeks, rose again to 23·4 during the week ending March 25th and exceeded by 2·5 per 1000 the mean rate during the same period in the thirty three large English towns. The rates in the eight Scotch towns ranged from 10·8 in Aberdeen and 17·6 in Leith to 25·7 in Greenock and 27·3 in Glasgow. The 659 deaths in these

towns included 51 which were referred to measles, 16 to whooping-cough, 13 to diarrhoea, 10 to scarlet fever, 8 to diphtheria, 4 to "fever" and 2 to small pox. In all, 104 deaths resulted from the principal zymotic diseases, against 95 and 71 in the preceding two weeks. These 104 deaths were equal to an annual rate of 3·7 per 1000, which exceeded by 1·6 the mean rate last week from the same diseases in the thirty three large English towns. The fatal cases of measles, which had declined from 53 to 45 in the preceding three weeks, rose again to 51 last week, of which 32 occurred in Glasgow, 8 in Dundee, 7 in Edinburgh and 4 in Paisley. The deaths referred to whooping cough exceeded by 10 the number in the previous week and included 14 in Glasgow. The fatal cases of scarlet fever, which had been 6 in each of the preceding two weeks, rose to 10 last week, of which 6 occurred in Glasgow and 3 in Edinburgh. The deaths from diphtheria, which had declined in the previous four weeks from 10 to 6, rose again last week to 8 and included 3 in Edinburgh and 2 in Glasgow. The 2 fatal cases of small pox were recorded in Glasgow. The deaths referred to diseases of the respiratory organs in these towns which had declined from 171 to 136 in the preceding three weeks, rose again to 151 last week, but were 30 below the number in the corresponding week of last year. The causes of 51, or nearly 8 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN

The death rate in Dublin, which had been 25·2 and 26·0 per 1000 in the preceding two weeks, further rose to 26·7 during the week ending March 25th. During the past twelve weeks of the current quarter the death rate in the city has averaged 28·2 per 1000, the rate for the same period being 22·1 in London and 21·0 in Edinburgh. The 179 deaths in Dublin showed an increase of 5 upon the number in the preceding week, and included 8 which were referred to "fever," 3 to whooping cough, 1 to measles, and not one either to small pox, scarlet fever, diphtheria, or diarrhoea. In all, 12 deaths resulted from these principal zymotic diseases, equal to an annual rate of 1·8 per 1000, the zymotic death rate during the same period being 2·3 in London and 3·1 in Edinburgh. The deaths referred to different forms of "fever" which had been 6 and 3 in the preceding two weeks, rose to 8 last week. The fatal cases of whooping cough which had been 1 and 4 in the preceding two weeks declined again to 3 last week. The 179 deaths registered in Dublin last week included 33 of infants under one year of age and 40 of persons aged upwards of sixty years, the deaths both of infants and of elderly persons showed a further increase upon those recorded in recent weeks. Five inquest cases and 7 deaths from violence were registered, and 71, or more than a third, of the deaths occurred in public institutions. The causes of 8, or more than 4 per cent., of the deaths in the city last week were not certified.

THE SERVICES

MOVEMENTS IN THE MEDICAL STAFF

SURGEON CAPTAIN J. F. BATESON, Army Medical Staff lately attached to the Coldstream Guards has left for Cairo to take up his appointment in the Egyptian Army.

INDIA AND THE INDIAN MEDICAL SERVICES.

Surgeon Lieutenant Colonel Quill, Army Medical Staff, has been appointed to Medical Charge, Station Hospital, Kirkee, vice **Surgeon Major Bourke**. **Surgeon Captain Wade Brown**, Army Medical Staff, just arrived from England on fresh tour has been posted to general duty Bombay District. **Surgeon Major Barnes**, Army Medical Staff, has been transferred from general duty, Bombay District, to general duty Poona District. **Surgeon Captain Nelis**, Army Medical Staff, on arrival from England on fresh tour has been posted to general duty Poona District. **Surgeon Captains Henderson and Healy**, Army Medical Staff, on arrival from England on fresh tour have been posted to general duty Bombay District. The services of **Surgeon Captain D. W. Scotland**, Civil Surgeon, Betul, are placed at the disposal of the Government of India Home Department. **Surgeon Major G. W. Robinson**, Army Medical Service doing duty Belgaum and Bangalore Districts is posted to the Medical Charge of the Station Hospital, Calicut. **Surgeon Major S. Hassan**, 3rd Bengal Ir-

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT

REPORTS OF MEDICAL OFFICERS OF HEALTH

Barnsley Rural Sanitary District—Two limited outbreaks of small pox occurred in the district in 1892. The first arose from a case which was under treatment for a week before its real nature was recognised and notified. From this case ten other cases arose. The second outbreak had its origin, under somewhat peculiar circumstances, from a case which was isolated in the hospital. The patient, a male adult, became suddenly delirious, overpowered the nurse who was temporarily left in charge of him, and effected his escape. He was immediately pursued and captured before entering any dwelling, but out of a small crowd which collected around him in the street no less than six persons contracted the disease. It would have been a point of some interest had the report stated whether these individuals had actually come into contact with the patient or not. These six infected five others, and one of these latter yet another four. Of the total number of cases which occurred during the year only one, some sixteen years previously, had been revaccinated. Dr Sadler, in his report, tells us that the nature of this case would have been doubtful had not others of a more pronounced and serious nature arisen from it. One of the patients who contracted the disease was well pitted by a former attack. The general death rate of this district during the year was 20·28 per 1000, and the infantile mortality 180 per 1000 registered births.

Godstone Rural Sanitary District—During the year 1892 the general death rate of the district amounted to only 12·9 per 1000, the rates in the different localities varying from 9·9 to 22·7. The infantile mortality was 118 per 1000 births, the zymotic death rate is not given. There was an extensive outbreak of diphtheria at the Church Missionary Home, Limpsfield. It appears that in the autumn of 1891 a few cases occurred, and the children were in consequence dismissed for the Christmas holidays. On their return, Jan 15th, several children are stated to have had some slight throat affection which required treatment, but it was not considered necessary to seclude them. Other cases of a similar nature continued to crop up, until, on March 18th, one was declared to be diphtheria. From this case it seems no less than twenty-two cases were infected. The report before us does not state whether any of those children who suffered from sore throats on the reassembling of the school were the same as those attacked with diphtheria prior to the Christmas holidays, and this point, in face of the view held by Dr Astley Gresswell on the recrudescence of diphtheria, becomes of importance. Dr Oldman very rightly insists upon the desirability of the frequent and systematic examination of the throats of school children, with a view to early treatment and isolation. It appears however, that the cases suffering from sore throat which occurred upon the reassembling of the school in question were examined and treated, but not isolated. In view of the admitted difficulty of diagnosing diphtheria it becomes an important question whether any form of sore throat occurring amongst school children should not at once be isolated. Dr Oldman's report gives a very complete introduction and a detailed account of each locality, but the matters treated of are, for the most part, of purely local interest.

West Hartlepool Urban Sanitary District—Dr Gourley again urges upon this authority the great importance of their providing a properly equipped hospital for infectious diseases, and he also draws attention to the need for some arrangements by which people whose houses are being disinfected may receive temporary shelter. The report states that thirty-two cases were removed during the year to the Port Sanitary Hospital, but that, owing to the deep-rooted objection there is to the place, great pressure had in several instances to be exerted. A limited outbreak of small pox apparently arose from a modified case of the disease, which was at first regarded as varicella. A destructor is much needed for the district, as also is an abattoir. During the prevalence of cholera in Hamburg a careful watch was kept by the inspector on all fruit arriving from abroad. West Hartlepool is, as Dr Gourley states, especially liable to have cholera introduced into it, owing to the transit of rags, and also of a number of emigrants who disembark here en route for America. It is, however, not altogether reassuring

to read that the survey of the sewers, which is being carried out by the borough engineer, continues to reveal very grave sanitary defects. These defects are being remedied as far as practicable with the funds voted each year for that purpose. It is regrettable that, in view of the special danger to which the borough is exposed, more money is not forthcoming.

Aston Manor Urban Sanitary District—The sanitary authority of this district presents an interesting example of the thoughtless manner in which some authorities embrace the adoptive Acts. Aston Manor has adopted the Infectious Diseases Prevention Act, and yet has provided no mortuary for the reception of bodies dead of infectious disease. Notification has worked successfully through the year, and isolation of the first case in a household has rarely failed to limit the outbreak to that case. Under the head of diphtheria we are told there have been eighty-three cases notified and two deaths. This is certainly a remarkably low mortality, and we should have been glad of further information as regards the age distribution in these cases. There has been a very considerable falling off in the number of scarlet fever admissions into the fever hospital during this year, 23 per cent only of the notified cases being admitted, as against 37 per cent in the year previously. Mr May is inclined to attribute this falling off to the mildness of the disease which prevailed last year and the unwillingness of parents under these circumstances to part with their children. About 150 of the scarlet fever cases which occurred in this district were considered by Mr May to be due to the consumption of infected milk. The zymotic death rate of the district during the year was 2·6 and the general death rate 16·4 per 1000. Infantile mortality was 152 per 1000 registered births. The sanitary state and requirements of Aston Manor are fully treated of in the report.

Plympton St Mary Rural Sanitary District—Dr Willoughby, in presenting his first annual report to his authority, gives a most interesting account of an outbreak of enteric fever, which might have, in all probability, been completely prevented, had the Notification Act been in force in the district. We give the account in the words of the report—"At Plymouth an epidemic of typhoid fever broke out, and the origin of the epidemic was investigated by the Health Officer. It was found that the patients were receiving their milk supply and other dairy produce from a farm in the district of the Plympton Sanitary Authority—but on inquiry at this farm the existence of any illness of the sort was denied. It was however ascertained that there were two cases of typhoid fever at this farm, and had been for some weeks, and one case was at the farm at the time of the denial. The result was that seventeen cases of typhoid fever occurred at Plympton, including one fatal case. On the farm being closed as a dairy farm no further cases occurred." Although the report does not give an exact account of the manner in which infection was introduced into the milk or water supply, it seems there was no reasonable doubt as to the milk being the carrier of the infection. Further on in the report we read that "in the autumn of the year a motion for the adoption of the Infectious Diseases Notification Act was again rejected by a small majority." Can there be a much stronger argument than the above for the Act in question being made compulsory?

St Neot's Rural Sanitary District—Mr Wright, in a general introduction to his annual report for this and other districts, refers to the deleterious effects of the School Board regulations upon the health of young children in rural districts. He draws attention to the manner in which parents in order to avoid the fines for non attendance, send their children long distances to school in wet and stormy weather, one of the results being that they have to sit for several hours in wet clothing. To discuss this point would open up a big question, but it is surely one of the duties of school teachers to pay such attention to the general condition of pupils under their care as to see that no preventable risk is run by their sitting in wet clothing &c. However, we are far from denying that there are not, from a public health point of view at least, many very serious drawbacks connected with compulsory education. Energetic steps are being taken in this district to prevent the pollution of the River Kim. The death rate during the year has been a high one for a rural district—namely, 19·54 per 1000. Twenty-four deaths were registered as due to influenza. Mr Wright is trying an experiment in one of the villages of this district by forcing water from a well through a specially adapted filter fitted to the pump. He maintains that, so far, the experiment has been highly successful, and he hopes after

expressing the opinion that it is possible some substance may have been discovered capable of withstanding projectiles of the highest penetrating power, he points out that no commission has yet reported on it, and that the tests stated to have been applied cannot be accepted as conclusive. He adds also that even in case of its bullet-proof properties becoming established there are numerous hindrances against its practical application in warfare. Professor Billroth shrewdly remarks that he should have considered the experiments reported as more satisfactory had Herr Dowe worn the jacket and allowed himself to be made the target. Considering the matter from the point of modern surgery, he points out that half the wounds received in battle are in the head and upper and lower limbs. It seems to us that the weight and flexibility of this bullet-proof material are most important elements. If it is of the nature of an inflexible, heavy cuirass which is only capable of being applied to some limited part of the body it will prove of very little actual use in warfare. It would indeed be strange if a reduction in the army medical establishments of Europe were brought about by a mechanical invention causing a great decrease in the number of the wounded required to be attended to. Moreover, if the bullet-proof property of Herr Dowe's invention turns out to be a fact its application to naval vessels as a substitute for armour plating is pretty certain to be tried.

"VIXERE PORTES ANTE AGAMEMNONA"

To the Editors of THE LANCET

SIRS.—It must have occurred to the hearers and readers of the Croonian Lecture to ask how it is that Englishmen have to learn about Francis Glisson from Professor Virchow. One meets with Glisson's name in German and French literature frequently. Is it not time something was done by our corporations or universities to help Englishmen to get some knowledge of medical history? Every year there is a Hunterian and a Harveian Oration. Brilliant as was the last Hunterian Oration, I think it would have been more profitable and more fitting to have heard Mr Bryant, practical surgeon and member of the staff of Guy's Hospital, on the life and works of Astley Cooper. Therefore I would suggest that in future Harveian and Hunterian orators should be allowed to take for their theme the work of any bygone British physician or surgeon worthy of being so noticed.

In the literature of the Continent, where medical history is officially recognised and privately respected, one sees the fame of Harvey and Hunter treated with something like a sense of proportion, and, illustrious as is that fame, it does not throw the reputation of all others of our great medical countrymen into the shade. In the glorious names of Sydenham, of Willis of Heberden, of Pott, of the Bells of Hall, of Blundell, of Syme and of Williams in the name of the famous Dublin School of Surgery, and, once more, in the noble names of Francis Glisson and Astley Cooper I would invite your attention and that of your readers to this question.

I am, Sirs, yours obediently,

London, March, 1893.

C B KEETLEY

THE INFERIOR LARYNGEAL NERVE A REPLY

To the Editors of THE LANCET

SIRS.—In THE LANCET of March 11th Dr W Ramsay Smith has published an interesting criticism of my late father's (Dr Herbert Davies') paper "On the Relationship between the Phrenic and Recurrent Laryngeal Nerves, with an Explanation of the Circuitous Course of the Latter." Dr Smith urges three objections, and as two of them only concern my father's theory I propose to answer them and to endeavour to show that they are of little real value. Firstly he says "The rima glottidis does not appreciably change in size and shape in normal breathing and the recurrent laryngeals are not necessary to ordinary breathing. Respiration can go on after section of both recurrent laryngeals the rima glottidis having the patency it usually acquires after death." Now, although in man there is apparently during

quiet breathing no appreciable change in the width of the glottis, yet there exists in animals an undoubted rhythmical alternation in quiet respiration. It must be also borne in mind that the inferior laryngeals contain really two sets of motor fibres one set, which innervate the muscles, which are concerned in phonation, and which therefore act only during expiration, when the phrenic nerve is inactive and the diaphragm relaxed, and the other set, which dilate the glottis and act, therefore, during inspiration, when the phrenic nerve is acting and the diaphragm consequently contracting. There therefore evidently is a combined action between the dilator muscles of the glottis and the diaphragm. Again, it is stated in vol. iv of Foster's Text-book of Physiology that "when in a living animal both recurrent laryngeals are divided the glottis becomes narrowed, assuming what may be considered its natural dimension—namely, that proper to it after death, when muscular contractions have ceased. Owing to the narrowing the entrance and exit of air into and out of the larynx are less easy, and a certain amount of dyspnoea, especially obvious if the breathing be hurried may result, but the extent to which it occurs differs in different animals and indeed, in different individuals." This dyspnoea is easily understood when one considers that there is a distinct difference of the patency of the rima glottidis as shown by careful laryngoscopic examination during life and after death, the former being 14 mm. and the latter 5 mm. Experiments on animals have proved that after division of the recurrent laryngeals the vocal cords are drawn upwards and downwards during inspiration and thus tend to occlude the glottis and produce ultimate suffocation. The above considerations show sufficiently that the recurrent laryngeals are necessary to ordinary breathing.

Taking the first part of the second objection—namely, the difference in length between the two recurrent laryngeals—I could point out that there is a similar difference in length between the two phrenics, the right being shorter than the left, and therefore there is a direct correspondence in this between the phrenic and recurrent laryngeal nerve on each side. In the second part of this objection Dr W R. Smith refers to cases where, according to him, the recurrent laryngeal do not "recur." The best answer to this is found in the following quotation from John Hilton. He says, "Now it has fallen to my lot to see examples in the dissecting-room in which the inferior laryngeals did not wind round the arch of the aorta or the subclavian artery, yet the course of the nerve was, notwithstanding equally recurrent, thus clearly indicating it had no necessary relation with the subclavian or aorta." As a further proof of the necessity of the lengthening of these nerves may be mentioned the fact that they are now believed to belong not to the vagus proper, but to the spinal accessory. In an appended note to his paper my father explains the reason of the direct course of the superior laryngeal nerve and of the necessity of the arytenoideus being supplied by it. Suppose any irritation, as from a crumb should affect the laryngeal mucous membrane, it is necessary that it should be conveyed as rapidly as possible to the nerve centre in order that the rima glottidis may be closed at once to prevent descent of the crumb into the trachea, the motor impulse is sent direct through this motor filament of the superior laryngeal nerve to the arytenoideus, which is the most powerful constrictor of the glottis.

I am, Sirs, yours truly

Finsbury square March 16th, 1893.

ARTHUR T DAVIES.

"HOW UNION APPOINTMENTS ARE MADE"

To the Editors of THE LANCET

SIRS.—Will you kindly give me space to answer the letter of "M R C S" in your last issue? In the opinion of "M R C S" it is perfectly right that any man who buys a practice should be given the appointments in connexion with it whatever the claims of other candidates may be, and he goes so far as to say that ninety nine out of every hundred will add, "and rightly so too." I do not agree with this, nor do I think it is the universal opinion. "M R C S" has altogether ignored the main point of my letter wherein I objected to boards of guardians advertising union appointments already practically filled up, but goes on to draw a dismal picture of a man who has invested his capital in a country practice and does not secure all his predecessor's appointments. What does "M R C S" think of the well-qualified and experienced man

fantry, is granted furlough in and out of India (p a) for two years. Surgeon Captain P Mullane, M.D., 7th Bengal Infantry, is granted leave for one year. Surgeon Major M O'Dwyer, Civil Surgeon, Jullundur, has obtained special leave of absence for six months, from April 14th, 1893, or such subsequent date as he may avail himself of it.

NAVAL MEDICAL SERVICE.

The following appointments are announced. Staff Surgeon James O'B Williams to the *Tourmaline* (dated March 28th, 1893). Surgeons Joseph C Wood to the *Wildfire*, additional, for temporary service at Valmer Depot, and Thomas O Rowlands, M.B. to the *Wildfire* (both dated March 25th, 1893). O L W Buntin, M.B., E T Meagher and A S G Bell to the *Vivid*, F D Lumley and H E Tomlinson to the *Victory*, B B Gilpin to the *Pembroke* and F H A Clayton M.B., and P Lord M.B., to the *Excellent*, all additional (dated April 11th, 1893). F J A Dalton to the *Pembroke*, P M May to the *Vivid* additional, Richard Barnard to the *Sphinx*, Alexander G W Bourn to the *Redbreast* and Alfred Sturdee to the *Vivid*, additional (all dated March 27th, 1893).

VOLUNTEER CORPS

Rifle 2nd Volunteer Battalion, the Royal Fusiliers (City of London Regiment). George Trew Cattell, M.D., to be Surgeon Lieutenant (dated March 25th, 1893).—3rd Volunteer Battalion, the Cheshire Regiment. Surgeon Major G Okell to be Surgeon Lieutenant-Colonel (dated March 25th, 1893).—1st Volunteer Battalion, the Duke of Cornwall's Light Infantry. Caspar Robert Laurie, Gent., to be Surgeon Lieutenant (dated March 25th, 1893).—5th (Isle of Wight, Princess Beatrice's) Volunteer Battalion, the Hampshire Regiment. Kenneth Walter Ingleby Mackenzie, Gent., to be Surgeon Lieutenant (dated March 25th, 1893).—3rd (Morayshire) Volunteer Battalion, the Senforth Highlanders (Ross shire Buffs, the Duke of Albany's). Surgeon Major G Whyte, M.D., to be Surgeon Lieutenant-Colonel, to resign his commission, also to be permitted to retain his rank and to continue to wear the uniform of the Battalion on his retirement (dated March 25th, 1893).

THE VOLUNTEER OFFICERS' DECORATION

Thames District.—Surgeon Lieutenant Colonel D H Monckton, M.D. Commanding the Maidstone Company, Volunteer Medical Staff Corps.

THE SUMMER SESSION AT NETLEY

At the Summer Session of the Army Medical School, Netley, which will commence on Monday next, fourteen candidates for commissions in the Army Medical Staff and fifteen candidates for commissions in the Indian Medical Service will attend the course of instruction.

YOUNG SOLDIERS AND SERVICE IN INDIA.

The *Army and Navy Gazette* has a long article on this subject, founded upon a contribution from the Professor of Military Hygiene at Netley which our contemporary is unable to publish *in extenso*, but the salient points of which it concisely summarises. From a table furnished by Professor Notter of the annual average mortality per 1000 of European soldiers in India in different periods during the present century, it appears that in the period 1800-1830 the annual average mortality was 84.60, 1828-1844, 54.09, 1830-1856, 56.70, 1869-1878, 19.30, 1879-1888, 16.02 per 1000 of European soldiers in India. In 1888 the death rate was only 14.84 per 1000. Typhoid fever first appeared in the statistical returns for India in 1861. During the ten years 1870-79 the mortality from enteric fever in the army of India averaged 2.03 per 1000, during the six years 1880-85 it was 2.98, in 1887 it rose to 3.76, and in 1888 it was 3.75 per 1000. The explanation of this increase in enteric fever, with a concurrent decrease in other fevers, is, no doubt, that it is partly attributable to a difference in nomenclature, but other factors are also present, and amongst the chief of these Professor Notter includes the large proportion of young soldiers now serving in India compared with former years, and, in addition, the still more important factor of new arrivals in the country. Under the short service system the proportion of men serving in India under five years is far larger, of course, than it was formerly. In 1871 the proportion was 64.6 of the total number, in 1888 it was 75.8. "The increased prevalence of enteric fever in India has, therefore, been accompanied by, and is possibly dependent on, an increase in the number of young and recently arrived soldiers." All this has been so frequently repeated, however, that it has become an old story, and the facts are

almost universally admitted. The *Army and Navy Gazette* draws the moral that in preparing the relief programme those regiments should as far as possible be sent on to India which have a large leaven of older soldiers, so that the younger ones may be sent away to the hills for the hot weather, and that, when matters can be arranged, battalions should undergo a process of acclimatisation by being moved on eastward from the Mediterranean and Egypt instead of being sent to India straight from England.

THE PHYSICAL AND SOCIAL TRAINING OF YOUNG OFFICERS.

We are glad to notice that our contemporary, the *Broad Arrow*, calls attention to the reports of the boards of visitors to the institutions for training of military cadets. The defects dwelt upon, as far as regards the Royal Military Academy at Woolwich is concerned, are on the physical side and as regards the Royal Military College at Sandhurst of a social kind. The latter do not concern us, but the former come within our purview as a question of health and hygiene. The bathing arrangements for the cadets at Woolwich are unsatisfactory. It is not so much a question of the use of cold water for baths in winter as the unsuitable and uncomfortable character of the arrangements. The bath rooms are small and uncomfortable, with sloppy floors and splashed walls. The passages are cold and draughty, and the provision for warming and a fair amount of comfort during the cadet's subsequent dressing is inadequate. Anything like a system of coddling for healthy boys is to be deprecated, but cadets are liable to catarrhs and influenza like other people. They have to go to an early parade, too, where they must of necessity stand still in the ranks after all this preliminary preparation for "catching cold." Their success at a military college depends upon the maintenance of their health, and their parents have to pay for them whilst there, consequently they are fairly entitled to a reasonable amount of provision being made for their health and comfort. It is not surprising that in the report of the visitors for 1892 we are told that about one fifth of the whole number of the cadets were admitted to hospital for bronchitis and sore-throat. The hospital, moreover, is said to be quite inadequate and unsuitable for the purpose.

MEDICAL AFFAIRS UNDER THE NEW RÉGIME IN EGYPT

Before the late change in the Egyptian Cabinet the appointment of Surgeon Captain Pinching of the Medical Staff as Inspector General of the Sanitary Department, with a salary of £1000 a year, had passed the ordeal of the Financial Committee, and was only awaiting what was supposed to be the formality of Ministerial sanction to become *un fait accompli*. Riaz Pasha, however, has now interposed his veto, and, as diplomatic pressure is not forthcoming, the matter has been allowed to drop.

THE FRENCH IN DAHOMEY

The question of the maintenance of an army of occupation in Dahomey is a serious one for the consideration of the French Government at the present time. The climate is notoriously unhealthy, and any prolonged sojourn on the West African coast will entail a good deal of sickness and invaliding amongst the French troops, with periodical drafts from France to make up the losses. We can well understand that the French Government is desirous of conferring with General Dodds as to the present aspect of affairs and the General's future plans, for, apart from the fact that King Behanzin and the Dahomeyans have not been so crushed as to be unable to offer further resistance and give trouble in the future, there is the permanent enemy of an unhealthy climate, with fever and dysentery, to be taken into account and this means a constant drain upon the French army and treasury.

BULLET PROOF CUIRASSES

The alleged invention of a bullet proof clothing by a tailor named Dove of Mannheim has aroused great interest in Austria, Germany and elsewhere. The intelligence was naturally entirely disbelieved at first and is still, of course, regarded with a good deal of incredulity. Several experiments are alleged to have been made, however, with the bullet proof material in Germany and it is said that bullets from a seven millimetre rifle did not penetrate it at a distance of 400 300 or even 200 yards. The exact composition of the material used is kept secret, but the cuirass is described as weighing 6lbs, as being about one and a half centimetres thick, and not flexible. Herr von Mannlicher has been interviewed on the subject, and, whilst

them being the Bridgewater trustees. As is usual in such cases, there will be plenty of objectors to this project of the corporation for obtaining a suitable site for the disposal of their refuse but there is no valid reason for believing that harm will be done to anyone or that the uninhabited district of Cadishead Moss will be in any sense prejudiced by the contemplated action of the corporation.

March 28th.

BIRMINGHAM

(FROM OUR OWN CORRESPONDENT)

The Queen's Hospital

THE annual meeting of the board of this hospital was held on March 22nd, under the presidency of the Earl of Dudley. The chairman of the board (Alderman Clayton) said that there were three matters in the report of considerable interest: the increase in the number of the beds, the re-arrangement of the casualty ward, and the question of finance. He alluded to these in detail. He pointed out that nineteen twentieths of the casualty patients were seen twice, on the second visit they would be charged a registration fee. This was an important departure in the conduct of such cases, which might call for criticism. Mr Bennet May, chairman of the Medical Committee, said that the year had been a full and satisfactory one, though there had been no very striking features to attract attention. A special vote of thanks was passed to the working men of Birmingham for the £1741 15s 9d contributed from the Hospital Saturday funds.

The Women's Hospital

The annual meeting was held on March 23rd the mayor presiding. The report showed that the number of new patients treated at the out-patient department had been 2569, a decrease of 141 compared with last year, the number of in patients admitted had been 277, an increase of 67. The committee regretted the loss of Mr Tait and desired to record their sense of the valuable services he had rendered to the hospital since he had been elected its consulting surgeon. The financial report showed an excess of expenditure over income. Various votes of thanks were passed.

Medical Trial

At the recent assizes Dr Evans brought an action against the proprietors of the *Birmingham Daily Post* for an alleged libel contained in an article published on Dec. 29th, 1889. The jury awarded him a verdict with £75 damages.

Mason College

The annual report has just been issued. It states that the total expenditure was £11,436 12s 7d and the income £10,275 10s 7d. The great event of the year has been the transference of the Queen's Faculty of Medicine. The report deals with the growth and prosperity of the college and gives a number of interesting details.

March 28th.

LIVERPOOL

(FROM OUR OWN CORRESPONDENT)

The Liverpool Eye and Ear Infirmary

MR EDGAR BROWN, the senior surgeon to the Liverpool Eye and Ear Infirmary, has just concluded a very successful course of lectures at the hospital, which has been attended by many local medical practitioners and others coming from a considerable distance. Mr C G Lee has delivered three lectures on Diseases of the Ear, the last of which was given on March 27th. These lectures are of a clinical character and are illustrated by patients. The attendance of patients is very large, and the surgeons have very favourable opportunities of demonstrating diseases of the eye and ear in all their forms.

The Liverpool School for the Deaf and Dumb

Though not medical institutions in the strict sense of the word schools and institutions for deaf mutes are of great interest to all medical practitioners. The Liverpool School for the Deaf and Dumb commenced as a very modest institution in 1825. In 1839 the present school was erected on the site of the old Botanic Garden and opened in October 1840. The school has given free education to all deaf and dumb children in the city and neighbourhood, boarders being re-

ceived for a moderate charge from those parents who are not in a position to pay more, whilst accommodation is afforded for the children of those who are in better circumstances and able to pay more. The school has recently sustained a great loss in the death of Mr Illingworth, the late Principal, and the committee will have some difficulty in replacing him.

The Assizes Accommodation for Medical Witnesses

Allusion has been made in previous letters to the entire want of proper accommodation for medical witnesses during the first few days of the assizes when they are waiting to be called before the grand jury. This has now been remedied, a commodious room in the west corridor of St George's Hall having been set apart for medical and other professional witnesses by the finance subcommittee of the city council, which has the control of this and other public buildings. As the assizes are held here four times yearly for the whole of south west Lancashire the attendance is required of many medical witnesses who will greatly appreciate this new arrangement for their convenience and comfort.

The Blackburn Murder

The trial of the youth aged sixteen for the murder of a chemist at Blackburn took place last week, ending in a verdict of manslaughter and a sentence of fifteen years' penal servitude. The prisoner, after being arrested on the charge, made a statement, not knowing what the medical evidence would be. The evidence of Dr Wheatley, surgeon to the Blackburn police, was to the effect that the wounds on the head of the deceased were more likely to be caused by a blow from a hammer held sideways than by striking the head against the floor. The prisoner's conduct after the tragedy showed great coolness and cunning.

The Homicides on Christmas Day and New Year's Day in Liverpool

A man was tried for the murder of his wife on the morning of Christmas Day and a young woman for the manslaughter of a man on New Year's Day. Both fatalities were the result of drink. In the former case, the woman's back was a mass of bruises and wounds, the causes of death being shock and hæmorrhage. In the other case, the man had received two wounds in the chest, both penetrating the pericardium, and one wounding the heart itself. Sentences of fourteen and seven years respectively were passed.

March 28th.

NORTHERN COUNTIES NOTES

(FROM OUR OWN CORRESPONDENT)

Whitley Convalescent Home

FROM the report presented at the annual meeting of the Whitley Convalescent Home by Dr Philipson it appears that the number of patients admitted last year was 1536 being 41 in excess of the previous year. The total number admitted since the institution was opened in 1869 has reached 24,753. The results are equally favourable as those given in previous reports. The financial state of the convalescent home is satisfactory although the receipts were less than in the previous year, the falling off being under the head of legacies, and the expenses were higher, owing to some necessary improvements.

Cumberland

Dr Lediard has concluded his course of lectures to ladies on nursing. The course has been very successful, there being more than 300 entered. Dr Lediard was the recipient of a testimonial from his class last week at the High School, Carlisle.

Small-pox

Cases of small pox have been reported from Carlisle, Penrith and Appleby. I see also that a fatal case has occurred at South Shields. It is stated that since the institution of compulsory baths for tramps at Kirby Stephen the visits of the tramping fraternity have diminished as has consequently the small pox. Still, unless the 'order of the bath' is made general at country workhouses, it will not do much good.

St Bees a Holiday Resort

The inhabitants of St. Bees which has great natural attractions as a seaside resort, are making an effort to develop and improve the place in this respect. The great railway companies are also aiding by placing St. Bees on their tourist system.

without capital whose only chance of obtaining a practice of his own is by getting an appointment to commence with and so work on? Is this man for ever to be only an assistant because, in the opinion of "M R C S," he has no right to apply for an appointment publicly advertised? Is it mena and unprofessional, as "M R C S" says it is, for him to try for such an appointment? I think not. It is essentially in the village class of practice that it is most desirable that a good man should be selected, as he has in all cases of emergency to rely solely on his own resources, yet, according to "M R C S," this responsible post should be given to a man merely because he can put down so much money.

It is said that at the College of Surgeons of Edinburgh a candidate, on being rejected at his final examination, asked the examiners to reconsider their decision, on the ground that he was *only* going to be a ship's surgeon. "All the more reason," said one examiner, "that you should be thoroughly up in your work, as there you will have no one to assist you." This applies with equal force to a village practitioner, usually miles away from his nearest medical confrère, and, therefore, the best man should be selected and not necessarily the one who buys the practice.

I am, Sirs, faithfully yours,

M R C P

March 27th, 1893

"CANCER PLASTERS"

To the Editors of THE LANCET

SIRS,—Dr S W Plummer in THE LANCET of March 25th calls attention to the serious consequences following the treatment of cancer by "quacks," and suggests "that if all such cases were reported it might lead to some more stringent regulations being adopted." In support of this suggestion, permit me to report a case now under my care in the Lincoln County Hospital. An ignorant woman has for some months (by false promises) misled the patient, who now, when it may be too late, has discovered her mistake. About six months after she first noticed a small lump in her right breast she consulted a medical man, who told her she had cancer and strongly recommended its removal. A month later she saw another medical man, who confirmed that opinion. Instead of following their advice, which would have saved her much suffering, she was persuaded by the quack woman to try her remedies which she declared, "would certainly cure the disease." For eight months almost to the time of being admitted into the hospital, the patient continued the treatment by ointment, pills and medicine advised by this woman, at an average cost of 3s per week, with the result that the tumour enormously increased, implicating skin, glands and muscles. A most extensive and serious operation was now found to be necessary. This was performed. Although every particle of disease has, so far as can be detected, been removed, yet the chances of recurrence are very great after such serious delay. This is but one case out of many for the majority of cases of cancer—at any rate, in Lincolnshire—are allowed to advance till the chances of eradicating the disease are lost. Ought this reckless cause of suffering and loss of life to be allowed to continue unchecked?

I am, Sirs, yours truly

W J CANT, L R C P Lond, M R C S,
Consulting Surgeon, Lincoln General Dispensary, Hon.
Surgeon, Lincoln County Hospital

March 27th, 1893.

MANCHESTER

(FROM OUR OWN CORRESPONDENT)

Termination of the Cotton Strike

AFTER many months of fruitless struggle between employers and employed, a compromise has at length been agreed upon, the basis of settlement being a reduction of 7d in the pound, or nearly 3 per cent., on the old rate of wages. Although the continuance of the strike through the winter months must have been attended by great privation to many thousands of Manchester cotton hands, nevertheless there appears to have been no corresponding increase, either in the amount of pauperism or in the proportion of persons on the sick lists of the several medical charities of the city. Some explanation of this fact may be found in the circumstance that, although the battle between employers and men has been chiefly fought out in Manchester, nevertheless the districts chiefly affected by the strike are comprised within the areas of the smaller towns

just outside the cess area rather than within the boundaries of Manchester itself. It is to be hoped that the recent disputes between employers and employed will have borne fruit in at least one important direction. In the course of the several conferences which were held in Manchester with a view to a settlement of the points in dispute certain agreements were arrived at which, it is hoped, will prevent a recurrence of such profitless squabbles in future. For instance, the appointment of a standing consultative committee has been decided upon, fully representative of the interests alike of masters and men, who will confer from time to time on all matters affecting the interests of the several branches of the cotton trade and make known their recommendations in the proper quarter. If this arrangement be faithfully and loyally carried out by all parties concerned there is every hope that we have seen the last of these disastrous and discreditableness interferences with commerce in Lancashire and its vicinity.

The Small pox Epidemic

As yet there are no indications that the end of the small pox epidemic is approaching. The reported cases within the three weeks ending March 18th have steadily increased from ten per week to twenty nine, and although in the week ending on Saturday last the numbers reported did not exceed nine, nevertheless the distribution of infection seems still to be very general, and at least eight of the eleven sanitary areas of the city are reported to have sent cases to hospital within the last few weeks. As is the case elsewhere, the workhouse tramp wards and common lodging houses of the city are the places from which most of the cases of small pox are removed, and although it is true that these places are, or may be, fairly well kept under supervision by the authorities, still it remains the fact that persons of the common lodging house or "tramp" class are difficult to deal with and, because of their nomadic habits, are peculiarly liable to carry infection with them from infected to non infected localities. Revaccination does not seem as yet to have been had recourse to by the poorer class of Manchester residents to anything like the extent which is necessary for their efficient protection against small pox. The guardians of the three unions constituting the city have been very active in issuing printed notices and in making special arrangements with the public vaccinators, but hitherto the official reports show that, practically, revaccination has been almost entirely neglected by the class of people who are most in need of protection. But although the legally constituted authorities for the promotion of revaccination are less successful than one could wish, it is satisfactory to find that the Jewish Board of Guardians, a voluntary association for the relief of the poor belonging to that community, have been much more successful. The expedient adopted by this enterprising board is that of making the granting of relief at the feast of the Passover conditional on the production by the candidate of a medical certificate to the effect that both he and his family have been vaccinated or revaccinated, as the case may be, and as the operation is performed by all the public vaccinators free of charge the regulation of the board inflicts hardship on no one.

Manchester Guardians and the Cancer Hospital

In a recent letter I commented on the addition to our local charities of a new hospital for the treatment of persons suffering from this terrible malady. At the last meeting of the Manchester guardians an application was made to the board on behalf of the funds of this charity. Although nothing has as yet been decided upon, it is certain that the guardians will eventually give the Stanley Hospital their support for the reason that many of the poor for whose care and treatment the board are responsible will be eligible for admission to the hospital wards or for treatment as out patients of the institution.

Manchester Council and Cadishead Moss

The Cleansing Committee of the city council have at length succeeded in providing themselves with a suitable area for the reception of the vast residual amount of night soil and other manurial refuse from the city of Manchester, which cannot now be sent to the Carrington Estate. Cadishead Moss is nearly two square miles in extent, and is situated between the Manchester and Liverpool turnpike road on the one hand and the L and N W main line to Liverpool on the other. The land was reclaimed about thirty years since, and was divided under the powers of the Inclosure Commissioners' Act amongst the freeholders of the district, the principal of

BERLIN

(FROM OUR OWN CORRESPONDENT)

Professor Georg Lewin

The friends of Professor Georg Lewin, Privy Councillor on Medical Affairs and one of the directors of the Berlin Charité, celebrated the twenty fifth anniversary of his appointment to a chair in the University of Berlin yesterday.

The Berlin Polyclinics

The Medical Professional Union held a meeting here on March 23rd, and adopted the following resolution: "The medical men assembled to-day declare that the efforts at reform in the matter of the Berlin polyclinics must be directed first and foremost to the keeping away of patients who are able to pay from these institutions so far as this is compatible with the aims of medical instruction, and entrust the further conduct of the agitation to the Professional Union."

Professor Von Pettenkofer on the German Epidemic Bill &c

Professor von Pettenkofer is said to have expressed his disapproval of the Imperial Epidemic Bill, especially as regards isolation, disinfection, quarantine and the hampering of traffic at frontiers. He is also reported to have confirmed the news that Bavaria opposed the bill in the Federal Council, but was outvoted. Of the Dresden International Sanitary Conference, it is said, he expects nothing, because with the exception of the English delegates all the members are followers of Dr Koch and M. Pasteur, whereas the one and only thing needful is the improvement of general hygiene. He hopes that Professor Virchow will succeed in getting the Bill rejected in the Reichstag. He thinks it likely that cholera will break out again this year, but believes that South Germany, and especially Munich, has nothing to fear.

Professor Wilhelm Erb

Professor Wilhelm Erb of Heidelberg has been called to Vienna to succeed Dr Kahler as professor of clinical medicine there.

The German Clinics for Mental Diseases

A Clinic for Mental Diseases has been established in connexion with the University of Tübingen. There are now only three German Universities—Kiel, Giessen and Rostock—which are without such a clinic, and negotiations are in progress for the supply of this defect at Rostock.

Professor Koch

Professor Koch will give courses of instruction on cholera for specially selected medical officials next month.

The Victoria House

The Victoria House for the Tending of the Sick, which has now completed the first decade of its beneficent activity held its annual general meeting on the 19th inst. During the past year the number of the sisters has risen from 149 to 160. Ninety four of them are in the service of the hospitals of the city of Berlin, the others in other institutions here and elsewhere. Some of them were employed at Hamburg during the cholera epidemic. The income of the establishment was 67,078 marks its expenditure 67,097 marks. It has a fund of 257,165 marks, including a pension and relief fund of 56,713 marks.

The International Sanitary Conference

The Saxon Minister of Foreign Affairs gave a banquet on March 19th in honour of the delegates to the International Sanitary Conference now sitting at Dresden. Berlin, March 27th.

CREMATION—At a recent meeting of the Warrington Literary and Philosophical Society the subject of cremation was introduced by a paper read by Mr C E Richmond, F.R.C.S. The question was discussed under the following five aspects—religious, sanitary, economical, medical and emotional. These points were severally dealt with by the lecturer in a way which secured the concurrence of his auditors. After the lecture a speaker referred to the fact that the bodies of fifty eight persons who had died from small pox had been interred in the Warrington Cemetery, and he asked whether such interments might not be the cause of epidemics for if so no further argument was required to show the need of the universal practice of cremation.

SOCIETY OF APOTHECARIES OF LONDON—The following candidates have passed an Examination in the subjects indicated below—

Surgery—H. H. P. Cotton and E. C. Drake Westminster Hospital; J. Edwards W. S. Newton, and E. Williams London Hospital; M. Ferguson Bellevue College New York G. L. Godwin, Edinburgh E. A. Grafton, Montreal J. M. James St. Thomas Hospital H. W. Joyce and W. H. Reed King's College E. B. Pellatt, Royal Free Hospital W. J. Rogers St. Bartholomew's Hospital E. White, Bristol.

Medicine Forensic Medicine and Midwifery—A. H. Bygott and G. P. L. Gregory Queen's College Birmingham E. A. Grafton Montreal E. Johnstone Owens College Manchester, A. E. Kennedy, London Hospital W. Turner King's College.

Medicine and Midwifery—R. W. Prentice, King's College.

Medicine—E. C. Adams and H. T. Dutton, St. Bartholomew's Hospital W. S. Newton London Hospital W. E. Pain, Guy's Hospital, A. B. Sturges Yorkshure College Leeds.

Forensic Medicine and Midwifery—D. Berne and E. B. Pellatt Royal Free Hospital.

Forensic Medicine—H. S. Chavasse Birmingham and St. Mary's Hospital B. J. Macaulay, Middlesex Hospital A. J. Pett, Cambridge University and Leeds E. Williams, London Hospital.

Midwifery—M. Ferguson, Bellevue College New York T. M. Nair Madras Edinburg and St. Mary's Hospital F. S. Park Liverpool and Edinburgh W. J. Rogers St. Bartholomew's Hospital.

The diploma of the Society entitling the candidates to practise Medicine, Surgery and Midwifery, has been granted to the following gentlemen—

Messrs Berne Chavasse Cotton Drake Godwin, Grafton, James, Joyce Kennedy Newton, Park, Turner White and Williams.

ST MARY'S HOSPITAL—The prominent feature of the report read at the annual meeting of the friends of this hospital last week was the unsatisfactory condition of its finances. The chairman said that although the net increase in the receipts was larger than that of the preceding year yet that increase was entirely owing to the unwanted number of legacies bequeathed to the charity and he appealed to the generosity of the public to support an institution which had conferred such benefit on the suffering poor of the neighbourhood.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL—The forty fourth annual meeting of this hospital was held in the Bell Medical and Surgical Library and Institute on March 14th. The report stated that 2098 in patients and 14,242 out-patients had been treated during the year. The income for the past year was £7503 showing an increase of £37 as compared with the receipts of the previous year. The expenditure was £7883, an increase of £132 over that of the preceding year. It was stated that a horse ambulance had now been attached to the institution and was used in conveying patients to and from the hospital.

Sad Suicide of a Student

On Friday evening last a student who had failed at his registration examination at Durham took his life by a large dose of chloral hydrate. It was stated at the inquest that the poor boy, whose age was only sixteen, sat at the examination from Monday until Friday and had set his heart on passing, hence his disappointment.

A Long Service

This week Dr Thos Stanthorpe, who is medical officer to the Hexham Union workhouse, completed fifty years' service in that capacity, having been appointed on March 24th, 1843. Dr Stanthorpe has been in general practice for the past fifty five years. He is always busy with public duties, and if there is a professional meeting at Newcastle he is almost certain to be present.

Sunderland and North Durham Eye Infirmary

It is proposed to hold a grand bazaar on Monday next in aid of the Sunderland Eye Infirmary. It is to be opened by the Countess of Scarborough and is likely to be one of the largest entertainments of this nature ever held for a Sunderland charity, as over 600 tickets have been already sold.

Ambulance Review

It is proposed to hold an ambulance review of the principal centres in the northern counties this summer at Newcastle. The date is not yet fixed.

Newcastle-on Tyne, March 29th.

SCOTLAND

(FROM OUR OWN CORRESPONDENT)

Reopening of the Convalescent Hospital, Corstorphine

THIS hospital, which is connected with the Edinburgh Royal Infirmary, has been closed for several months owing to alterations and enlargements. These being completed, it was officially opened by the Marchioness of Tweeddale in the presence of the Lord Provost, some of the managers and staff of the Royal Infirmary and others. The Marchioness, who made a speech before declaring the new wards open, dwelt upon the necessity of such an institution in connexion with a large hospital where patients might regain strength after illness before returning to their homes and work. Two new wings have been added to the old building, giving two new dormitory wards containing twenty beds each, day rooms, bath rooms and other necessary accommodation. Changes have also been made in the kitchen arrangements and servants' accommodation. The hospital now has beds for 100 patients. In the new wards the beds are placed head to head in the centre of the ward, this being a plan adopted by the late Mr Fasson as giving more room. The additions and alterations cost about £8000.

Medical Examinations in Edinburgh

Last week the examinations for the University First Professional were held. The Second Professional begins this week. Next week the spring examinations for the Triple Qualification will commence.

March 28th.

IRELAND

(FROM OUR OWN CORRESPONDENT)

Health of Dublin during 1892

THE births registered in the Dublin Registration District during last year numbered 9699, or 28 per 1000 against 29 per 1000 last year, whilst the deaths were 10,214, or 29.2 against an average of 27.5 per 1000 for the past ten years. The total number of deaths from zymotic diseases, which had fallen from 1019 in 1890 to 865 in the following year, rose last year to 1500, or 26.2 over the average for the ten years 1882-91. The increase was chiefly due to the prevalence of measles for the greater part of the first half of the year and to the comparatively large number of deaths from influenza and its complications in the first quarter. The mortality from scarlet fever was only 21 deaths, against an average of 142 for the previous ten years, measles caused 472 deaths, typhus fever 9, typhoid fever 122, influenza 224 and whooping-cough 155. There were 3 cases of small pox treated in Dublin hospitals in 1892, but all recovered, and the disease has not proved fatal in the Dublin district since March, 1888.

National Hospital for Consumption

The report of the Executive Committee states that the sums promised to the building fund amount to £10,431 3s 6d, of which £9571 12s 6d have been received. The site for the hospital has been generously given by Earl Fitzwilliam free of rent, and plans of the building have been approved. The site consists of about nineteen acres, situated three miles inland, in the county of Wicklow. It is well sheltered and has a southern aspect, and the medical members of the committee have unanimously reported in its favour. It is proposed that the constitution and government of the hospital shall be incorporated under the Companies Act, 1867. It is intended that the buildings shall be erected on the plan of the Ventnor Hospital, in separate blocks, the extent of the building depending in the first instance upon the amount of annual support to be promised. With a view to secure an income for the maintenance of the hospital a member of the Executive Committee has generously offered to provide £100 per annum in perpetuity if a further sum of £900 per annum be promised for the present.

Sir Patrick Dun's Hospital, Dublin

A conversation in aid of the funds of this charity will be held in the Royal College of Physicians on April 20th, and a concert for the same purpose in the Examination Hall, Trinity College, on April 29th.

March 29th.

PARIS

(FROM OUR OWN CORRESPONDENT)

The Obstetrical Society of France

THE second session of this Society will be held at Paris in the small amphitheatre of the Faculty on April 5th, 6th and 7th. The subjects of discussion will be "Symphysiotomie" and "Les Services d'Accouchement en France."

Abuse of Charity in Hospitals

It is not an uncommon occurrence in this very thrifty land for rich provincial men to enter hospital for operation in order to shirk the fee payable to the surgeon operating *a domicile*. A scandalous incident of this kind has recently come to light in one of the Paris hospitals, the too economical occupant of the bed being an exceedingly wealthy suburban gentleman who duly underwent an operation under an assumed name. The circumstance having been brought to the notice of the Municipal Council, the two following resolutions, which I transcribe textually, were adopted: "Le Conseil (1) invite l'administration à prendre des mesures énergiques pour empêcher que des gens aisés et même riches se fassent opérer gratuitement dans nos hôpitaux, rendre beaucoup plus sévères les enquêtes sur la situation de personnes dont le domicile permanent à Paris n'est pas établi (2) À étudier l'application d'un prix de journée spécial pour les malades aisés."

A New Foot warmer for Cabs

In winter the word *chauffee* borne by Paris cabs denotes that a comforting foot warmer is provided in the interior of the vehicle. This practice has recently taken a great expansion, many omnibuses and trams being now similarly treated. But, however comforting such a provision may be to the shivering "fare," it is not always devoid of danger, many accidents having happened from the inhaling of deleterious gases evolved by the heating material. M. Loison de Viviers has recently solved the difficulty by the invention of an apparatus in which the heat procured by the slacking of lime (140 to 320 calories per kilogramme) is utilised. The warmer consists of two compartments, in one of which is placed some quicklime and in the other water, the latter being allowed, by an appropriate mechanical arrangement, to percolate slowly or quickly, and during any time desired, into the lime chamber. A temperature of 100° C is thus easily maintained for a time proportional to the capacity of the warmer.

A Hospital for Phthisis for Paris

In a former letter I drew attention to the crowding of the general hospitals of Paris with phthisical patients and to the inconvenience and danger resulting therefrom. The Assistance Publique is, with the approval of the Municipal Council about to remedy this state of things by the creation at Angicourt, in the Department of the Oise, of a hospital for phthisis.

March 27th.

The Use of the Revolver

The Marquis of Carmarthen asked the Secretary of State for the Home Department whether he had caused inquiries to be made among the officers of Great Britain as to the number of deaths caused by revolvers and, if so, whether he would communicate the result of those inquiries to the House. Mr. Asquith said he had caused inquiries to be made and had received a good deal of useful information from coroners and others. He hoped that all the replies to the circular which he had sent would have arrived shortly and when the information was complete the question would be considered whether it should be presented to the House.

Hospital Officers and the Income Tax

Sir Herbert Maxwell asked the Secretary to the Treasury whether it was the case that under 5 and 6 Vic. c. 25 Schedule A, Section 61, power was taken to assess for income tax the premises occupied by hospital officers and servants of hospitals and other charitable institutions even where such premises formed part of the main building and the salaries of such officials and servants when exceeding £150 per annum, were separately assessed for income tax, whether in fact it had been the practice to assess on such premises, and whether he would consider the expediency of providing for their exemption. Sir John Lubbock replied that the Act referred to granted allowance of the duties charged on Schedule A of the Income Tax on any hospital &c. in respect of public buildings and premises belonging to it and not occupied by any individual officer whose whole assessable income, however arising, amounted to £150. It had been and it was the practice to limit the charge to the annual value of the premises so occupied and to let the rest go free, and he did not see any ground for altering that practice.

Cholera Hospitals (Ireland) Bill

In the House of Lords on the 24th ult. this Bill was read a second time.

Licensing Reform

The Bishop of London presented a Bill dealing with this question, and the main purpose of it was to limit the number of places where intoxicating liquors were sold. Public houses his lordship maintained, should be under the control of the people themselves, and this control should be exercised by transferring the power of renewing licences from the magistracy to a board to be elected by the people. The Bill proposed that five years after the measure became law the number of public houses should be restricted according to the population of the district; this proposition, however, was a matter open to modification. The question of compensation moreover was one to be settled hereafter. Also it was desirable that clubs where intoxicating drinks were sold to the members should be subject to registration and be placed under proper regulations. The Bill was read a first time.

Vaccination and Smallpox

In answer to Mr. Pease, Sir W. Foster said that the vaccination returns for 1892 had not yet been received but with regard to Balesy appeared that in 1891 the number of children born in the borough was 842, of whom 142 died unvaccinated, the operation having been successfully performed in the remaining number. As to Warrington and Manchester the inquiries on the subject were undertaken by the Privy Council Commission on Vaccination and not by the Local Government Board. In reply to Dr. Farquharson Sir W. Foster said that Dr. Sidney Coultard had made inquiry on behalf of the Royal Commission in the circumstances connected with the smallpox outbreak in the Dewsbury district, as well as with regard to Leicester; the results of which would probably be included in the report of the Commission.

Importation of Diseased Cattle

Mr. Gardner said, in reply to a question put by Mr. Jeffreys, that the time which usually elapsed between the onset of symptoms and the exposure to the infection of pleuro pneumonia was about thirty days, which might extend to twice that number. In one instance in which a suspected animal was subjected to post-mortem examination by an expert the disease appeared to have existed for a long period, perhaps a year. In answer to further questions Mr. Gardner said he would consider whether it would be advisable that the Board of Agriculture should institute a series of scientific experiments with a view of throwing light on the question. As to the proposed examination of the lungs of cattle landed in this country from Canada, the arrangements had not yet been formulated but proper precautions would be adopted to prevent as far as possible the introduction of diseased animals into Canada and through that dependency into England.

The Army Medical Board

Mr. Kenny asked the Secretary of State for War whether the military authorities had decided to appoint the examiners for the Army Medical Board from the London College of Surgeons and, if so, whether it was intended to also appoint examiners from the Irish College of Surgeons and whether he was aware that the rumour that the Army Medical Board intended to confine their choice of examiners to the London College had given rise to a belief widespread in medical circles in Ireland that Irish candidates for the Army Medical Service would not receive fair consideration under such a system. Mr. Campbell-Bannerman: Yes, Sir, the examiners are now to be appointed for the limited time of four years and they will be taken from amongst the examiners of the Conjoint Board of England. I do not anticipate that this will have any prejudicial effect on the interests of the Scotch and the Irish School, a result to which I should personally be as reluctant to contribute as the hon. member himself.

Sanitation in Public Buildings

In Supply Mr. Hanbury called attention to the numerous defects discovered from time to time in the sanitary arrangements of public buildings the condition of the Houses of Parliament and that of the Royal Palace being mentioned as examples of these defects. Dr. McGregor said the money spent in this direction was simply wasted. The Sanitation of the Houses of Parliament was scandalous. Mr. Shaw Levee's remarks in view of the complaints raised by several of the speakers were to the effect that the structural defects of the building mentioned were exaggerated and that certain difficulties were in the way of improvements with respect to the defects which were known to exist.

Appointments.

Successful applicants for Vacancies Secretaries of Public Institutions and others possess no information available for this column, are invited to forward it to THE LANCET Office, directed to the Sub-Editor not later than 9 o'clock on the Thursday morning of each week for publication in the next number.

ADAMS S. H. M.D. Lond. M.R.C.S. has been appointed Medical Officer for the Bedford and Kemp on Sanitary Districts of the Bedford Union.

ALEXANDER, F. W. L.R.C.P., L.M. Edin., M.R.C.S. D.P.H. Eng., has been appointed Medical Officer for the Poplar and Bromley Combined Sanitary Districts.

BARRITT J. W. M.D. Ch.M. Melb. M.R.C.S. Eng. has been appointed Honorary Surgeon to the Victorian Eye and Ear Hospital, Victoria, Australia, vice Bowen resigned.

BARTLETT F. P. L.R.C.P. Lond., M.P.C.S. has been reappointed Medical Officer of the Cowra Hospital, New South Wales.

BOVEY D. J. W. M.B. C.M. Edin., has been appointed Medical Officer of Health for the Rural Sanitary District of the Lunsdale Union, vice Mackay, resigned.

BROWNE, D. G. M.D. Ch.M. Ire. has been appointed Medical Officer of the Narrandera Hospital, New South Wales.

BUTT F. J. M.B. C.M. Edin., has been appointed Medical Officer for the North Western Sanitary District of the Chester Union.

CLEGG RICHARD L.R.C.P. Lond., M.R.C.S. has been appointed Medical Officer and Public Vaccinator for the District of Clayton & Moors and Ebbw Vale, Blackburn Union, vice Illingworth, resigned.

COLLINGRIDGE, Wm. M.D. D.P.H. M.R.C.S. has been reappointed Medical Officer of Health for Port of London.

DETON W. H., M.B. Ch.M. Edin. M.R.C.S. has been appointed Public Vaccinator for Frankston, Victoria, Australia.

FINLAY Wm. M.D. San Francisco has been reappointed Medical Officer of the Young Hospital, New South Wales.

FLORANCE, E. M.D. Paris, has been appointed Medical Officer to the Brandwood Hospital, New South Wales, vice Llewellyn.

FORREST J. A. M.R. Ch.M. Edin. has been appointed Government Medical Officer at Charters Towers, Queensland, vice Paoli, resigned.

GIBBS J. W. M.D. Ch.M. Aberd. M.R.C.S. has been appointed Resident Medical Officer of the Adelaide Hospital, South Australia.

HAYDON H. W. M.R.C.S. has been appointed Medical Officer for the First Sanitary District of the St. Columba Major Union.

HATTS W. A. L.R.C.P. Lond. M.R.C.S. has been appointed Medical Officer for the Second Sanitary District of the Calne Union.

HEELEY J. T. L.R.C.P. Edin., L.S.A. has been reappointed Medical Officer of the Young Hospital, New South Wales.

HEYLAND H. K. M.D. Ch.D. B.M. has been appointed Public Vaccinator at Tanunda, South Australia.

HOGG R. B., M.R.C.S. L.S.A. Eng. has been appointed Senior House Surgeon to the Dunedin Hospital, New Zealand.

KEENEY D. L.R.C.P. L.V. L.R.C.S. Ire. has been appointed Medical Officer for the Workhouse St. James Union.

KEEPE R. S. L.R.C.S. Ire. has been appointed an Honorary Surgeon-Lieutenant on the Medical Staff of the New South Wales Volunteer Force.

MARSDEN R. W. M.B. V.C. L.R.C.P. Lond., M.R.C.S. has been appointed Assistant Medical Officer at the Crumpsall Workhouse, Township of Manchester.

MILLER, J. T. ROGER, L.S.A. Lond. has been reappointed Medical Officer and Public Vaccinator for the Leavening District of the Walton Union.

MITCHELL, Jas., M.B. Ch.M. Aberd. has been appointed Medical Officer of the Narrandera Hospital, New South Wales.

NORRIS Wm. P. M.B. Ch.B. Melb. has been appointed Public Vaccinator at Lilldale, Victoria, Australia.

O'DONNELL E. J. F.R.C.S. L.M. R.Q.C.P. Ire. has been appointed Honorary Medical Officer to the Prevention of Cruelty Society, Queensland.

O'MEEHAN J. A. L.R.C.S. Ire., has been appointed Medical Officer of Health at York, Western Australia.

ROBERTS FRANCIS H., L.R.C.P. Lond. M.R.C.S. has been reappointed Medical Officer of Health for the Llandudno Wells Urban Sanitary District.

SAUNDERS M. P. L.R.C.P. Lond. has been appointed Medical Officer for the Hacknall to Liverpool Sanitary District of the Basford Union.

SHYMS Wm. ST. CLAIR, M.B. Aberd. has been appointed Pathologist to the County Asylum, Pres. wh. Llanerch.

THOMAS JABEZ, F.R.C.S. Eng. L.M. L.R.C.P. F.P.C.S. Edin. has been reappointed Medical Officer at the Swansea Tunnels Works.

TEBBY A. H. M.S. Lond. F.R.C.S. Eng. has been appointed Surgeon to Outpatients at the Evelina Hospital for Sick Children, Southwark-bridge-road, vice Eve appointed Surgeon to Inpatients.

WEBSTER, P. S. M.D. Dm. M.R.C.S. L.R.C.P. Lond. has been appointed Honorary Assistant Surgeon to the Victorian Eye and Ear Hospital, Victoria, Australia.

WHITCOMBE, P., M.R.C.S. has been reappointed Medical Officer for the Hospitals at Denton.

WHITE, J. MACKIE, M.A., M.B. Edin., has been appointed Physician to the Dundee Royal Infirmary, vice Dr. Nicolson, deceased.

WILLS ERNEST M.D. L.R.C.P. Lond. M.R.C.S., has been appointed as is in Medical Officer to the County Asylum, Ebbw Vale, Lancashire, also as a Medical Officer to the Claybury Asylum, Woodford, Essex.

NEW INFIRMARY AT HALIFAX—The memorial stone of the new infirmary at Halifax will, it is understood, be laid on June 17th, when representatives of various public bodies will be present. The occasion will be marked by a somewhat elaborate ceremonial.

ST BARTHOLOMEW'S HOSPITAL, CHATHAM—The twenty-ninth annual report of the trustees of this charity gives a favourable account of the beneficent work effected during the past year. Regret was expressed that ill health had deprived the institution of the services of Mr A W Nankivell, who for more than twenty-five years had acted as house surgeon. A scheme is in progress, subject to the approval of the Charity Commissioners, providing that five medical practitioners residing in the neighbourhood shall be appointed honorary medical officers of the hospital to take charge of wards.

THE METROPOLITAN HOSPITAL—The annual meeting of this hospital was held on Thursday, March 24th, at the institution in Kingsland road, London, Mr C J Thomas, C C, presiding. The report showed an increase in the number of in-patients from 860 to 887 and of the out-patients from 69,196 to 71,754. The receipts amounted to £7004 and the expenditure to £8885. Through lack of funds the committee had been obliged to close twenty-four of the beds. The chairman, in moving the adoption of the report, earnestly appealed for help and said that the committee felt bound to raise another £4000 in the shape of a charge on the estate.

UNIVERSITY COLLEGE HOSPITAL—Mr Henry Lucas, chairman of the hospital committee, occupied the chair at the annual meeting of the above institution, which was held in the board room on March 24th. In moving the adoption of the report the chairman said that 2799 in-patients had been treated during the year. The percentage of deaths on all operations had fallen from 16.7 in 1875-76 to 7.3 in 1889-90, on major amputations, from 26.7 to 9.0. Last year's debt of £17,000 had been reduced to £6000. Increased accommodation was required, and for this purpose £30,000 would be necessary before rebuilding could be commenced. Of this sum £28,000 had been raised or promised. The report was unanimously adopted.

BEQUESTS AND DONATIONS TO HOSPITALS—The late Mr Charles Ganderton of Pershore bequeathed £7000 to the Worcester Infirmary, and also the residue of his estate after payment of certain legacies. He also bequeathed £500 towards founding a cottage hospital at Pershore. The Secretary of the British Home for Incurables has received a further donation of £250 from Mr Pinder Simpson, thus completing a donation of £500 and founding a pension in connection with the institution, to be known as the Mrs Eliza Holm Pension. The late Mr B M Kenworthy bequeathed £1000 to the Ashton under Lyne Infirmary. Mr Samuel H Burrows late of Broomfield, Sheffield, bequeathed £250 each to the Sheffield General Infirmary, the Sheffield Public Hospital and Dispensary and the Jessop Hospital for Women and £100 to the Children's Hospital. The late Mr William Hodgson bequeathed £500 to the York Lunatic Asylum. Mr Thomson Hankey, late of Portland place, London, bequeathed £100 each to Guy's Hospital, St Thomas's Hospital, the City Dispensary and the Royal Sea Bathing Infirmary, Margate, and £200 to the City of London Truss Society. The late Mr William Leatham Barclay of The Briars, Regent, bequeathed £500 to the North Eastern Hospital for Children, London. The Goldsmiths' Livery Company have made a grant of £200 to the Metropolitan Hospital, Kingsland road. The late Miss Christie of Hill terrace, Arbroath, bequeathed £1000 to the Arbroath Infirmary. Mrs Jane Freeman, late of Southwam, Halifax, bequeathed £500 to the Halifax Infirmary and £100 to the Harrogate Bath Hospital. Mr J M Savage (a trustee of a fund left by Mrs Savage for charitable purposes) has contributed £105 to the New Brighton Convalescent Home. The following legacies have been bequeathed by the late Sir Andrew Barclay Walker of Osmaston Manor, Derbyshire, to the undermentioned Liverpool institutions: Royal Infirmary, £1000, Royal Southern Hospital, £1000, Northern Hospital, £1000, Stanley Hospital, £500, Liverpool Eye and Ear Infirmary, £300, Liverpool Consumption Hospital, £500, Liverpool Infirmary for Children, £500, Liverpool Home for Incurables, £500, and to the Ayr Infirmary for Children, £1000.

ROYAL COLLEGE OF SURGEONS IN IRELAND—FELLOWSHIP EXAMINATION—Mr Edward Leates, L.R.C.P.I. and L.R.C.S.I., having passed the necessary examination, has been admitted a Fellow of the College.

THE ROYAL BRITISH NURSES' ASSOCIATION—On Thursday, March 23rd Dr F Foord Caiger (Medical Superintendent of the Fever Hospital, Stockwell) delivered the first of two lectures on Fevers and Fever Nursing to the members of the above association at 3, Hanover square, W. The lecturer dealt in a practical way with the classification, the symptoms and the periods and means of infection of fevers. The second lecture will be delivered at 20, Hanover square, on April 27th, by Dr Caiger, when he will describe the most approved methods of nursing.

THE METROPOLITAN ASYLUMS BOARD—The fortnightly meeting of this board was held at the offices of the London County Council on March 18th, when Sir Edwin Glasworthy presided. The returns showed that 491 fever patients had been admitted during the fortnight, 75 had died, 660 had been discharged recovered, and 2295 remained under treatment, of whom 1971 were scarlet fever patients, 271 diphtheria, 3 typhus fever and 48 enteric fever patients. These figures showed a decrease as compared with the numbers remaining under treatment in the previous fortnight of 244. In regard to small pox 102 patients had been admitted, seven had died, 59 had been discharged, and 297 remained under treatment, as compared with 171 in the preceding fortnight, an increase of 36. Mr Augustus Scovell presented the report of the Ambulance Committee, which stated that small pox was spreading in the metropolis in every direction, chiefly through the influence of tramps and men out of work. The number of patients the board had received was composed almost entirely of adults, and there was no doubt that the spread of the disease was due in no slight degree to the insanitary state of some of the shelters and the absence of any stringent medical supervision. On the recommendation of the General Purposes Committee, it was decided to add the small pox hospital ships to the list of hospitals available for purposes of medical instruction.

NOTES IN PARLIAMENT

The Merchant Shipping Act

THE rules for the inspection of provisions and water under the Merchant Shipping Act 1892, are calculated to be of great service to our vast seafaring population. They are to apply to all ships leaving the United Kingdom and passing through the Suez Canal or round the Cape. The Inspector is appointed by the Board of Trade. All stores named in the Act as also water are subject to inspection. The inspection is to take place alongside the ship on shipboard, or elsewhere as determined by the authorities. All surplus stores and contents of casks are to be inspected under the same conditions as the original inspection. Passed stores need not be reinspected if the inspector be satisfied. This official must receive notice of a desired inspection forty-eight hours at least before a specified time. Firms supplying stores for shipment coastwise before leaving the kingdom may notify the Inspector under the same conditions as those required of the ships officer or agent. A complete list must be supplied for inspection. The hours during which an inspection may be made are from 10 A.M. till 5 P.M. and if matters are not ready at the specified time the inspection must be deferred. Requirements are specified as to the condition and carriage of beef, pork and preserved meat and vegetables. The Inspector has power to open tins containing provisions. The constitution and storage of biscuits are also dealt with, and the Inspector has power to go on board at any time and, if he find aught amiss to detain the ship until matters are remedied to his satisfaction. Water tanks must be cleaned before being filled afresh. Defective stores are to be landed. The certificate is to be granted at the final port of departure if the Inspector is satisfied on all points.

Haslar Hospital.

In the House of Commons on Thursday Mr Macfarlane asked the Secretary to the Admiralty if he was aware that medical officers at Haslar Hospital were not permitted to administer anaesthetics without leave from headquarters in London, whether the medical staff of the navy was short of its full complement of officers, and why if that were so there was no examination for new candidates in February. Mr Edmund Robertson who replied on behalf of the Secretary, stated that the medical officers at Haslar as at all other naval hospitals were permitted to administer anaesthetics whenever they considered it necessary to do so and they were under no obligation to refer to the Medical Department in London nor was there any record of such an application having been made. The medical staff of the navy was only three short of the full number in the estimates. Examinations were not now held in February, but in May and November as required.

Notes, Short Comments & Answers to Correspondents.

EDITORIAL NOTICE

It is most important that communications relating to the Editorial business of THE LANCET should be addressed exclusively "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office

Lectures, original articles, and reports should be written on one side only of the paper

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET should be addressed "To the Publisher."

We cannot undertake to return MSS not used

PUBLISHER'S NOTICE

IN ORDER to facilitate the work of reference to the volumes of THE LANCET, we have arranged in the future to publish duplicate copies of the Index to each half yearly volume in a form in which they may be subsequently filed or bound together.

We have had a large number of duplicate copies of the Index to the last half yearly volume printed, and those of our subscribers who may wish to be supplied with loose copies can obtain the same (without extra charge) on making application to the Publisher of THE LANCET.

RUPTURE OF INTESTINE CAUSED BY A TAPEWORM.

In the *New York Medical Journal* for Feb 11th Dr Dunlap of Donville reports a remarkable and very successful instance of intestinal surgery. He was called to a married lady who was suffering from the symptoms of shock and internal hemorrhage and he diagnosed a ruptured ectopic gestation, and immediately proceeded to open the abdomen. The pelvis was found to be full of recent blood-clot, but the generative organs were perfectly normal. On flushing out the abdomen a long tapeworm floated to the surface and on following it up it was found to protrude from a large ragged opening in the small intestine, and the head of the parasite was attached about twelve inches higher up. The opening in the bowel was an inch and a half long and involved about two thirds of the circumference of the bowel and its edges were ragged and gangrenous. The damaged part of the bowel was excised and the two ends were united by a continuous Lambert suture. The patient recovered. This case is of interest on account of the remarkable cause of the intestinal rupture, but it is still more valuable as another example of successful circular enterorrhaphy by simple means without any special appliances. Only a short time ago circular enterorrhaphy was condemned and various devices were introduced to accomplish the speedy and safe union of completely divided intestine. The most recent experience goes to show that the condemnation was too speedy and that the simple suture of the bowel is a really practical procedure.

"KISS THE BOOK SIR."

To the Editors of THE LANCET

SIRS—For the guidance of those members of our profession who desire to swear with uplifted hand but are told that they cannot be permitted to do so I beg to submit the law on the subject and to suggest that each medical reader of the following paragraph should cut it out and paste it into his visiting list for ready reference—

Oaths Act 1888

Section 5—If any person to whom an oath is administered desires to swear with uplifted hand in the form and manner in which an oath is usually administered in Scotland, he shall be permitted so to do, and the oath shall be administered to him in such form and manner without further question."

I am, Sirs yours truly
Kendal, March 21st, 1893.

MUSGRAVE CRATON

* We insert our correspondent's letter although we have repeatedly published Section 5 of the Oaths Act, 1888.—ED. L.

THE EFFECT OF CHANGE ON THE JADED LONDONER.

A PRACTITIONER sends us the following account which he has received from a patient who had from overwork and confinement in doors become seriously impaired in health, and whose appetite had completely gone. He gives it as an illustration of the immediate effect of change of environment, mode of life, meals and society upon the Jaded Londoner. In some places this effect is very marked notably at the seaside resorts on the east and south coasts. He writes: "Struck on former occasions with the effect of complete change I advised my patient to eat whatever he fancied and asked him to note the items of his diet on a piece of paper. The patient wrote that the following was the dietary of the first day: 'At eight o'clock I had one boiled egg, two biscuits and one cup of tea served in bed. After an hour's walk along the seashore I returned at ten to breakfast. It consisted of one fish, one boiled egg and a rash of bacon, one cup of coffee and a roll and butter, all of which I ate with pleasure. This was followed by a walk along the shore till twelve o'clock, when I had a bottle of stout, two biscuits and a piece of cheese. A brief ride on a bicycle made me wish for something cooling and at one o'clock I had a glass of Scotch whisky with lime juice and ate two bananas. I drove home to dinner and at half past two I was able to consume the following with much relish: A plate of mock turtle soup, one roll and a glass of sherry half a chicken, potatoes and cabbage, with one glass of burgundy and a piece of Gorgonzola cheese. I engaged an open boat for the afternoon and at five o'clock returned to a cup of tea and a bath bun. After enjoying myself with pleasant company, I returned to my hotel to partake of a piece of fricasseed rabbit, a piece of cheese and a glass of whisky toddy, before retiring to rest. I was much surprised at my own endurance, and in the evening I experienced a feeling of repose and content to which I had long been a stranger. This account does not include sweets, apples and oranges which were consumed during the day.' The improvement wrought by so brief a sojourn is hardly likely to be prolonged but as a restorative many can endorse the writer's experience of change of air."

Ialobe.—The cases in which excision would be justifiable are very few if any. The probability of nerve disturbance is so great that failure of perfect bony union might be met with. 'Perfect general health is very rarely if indeed ever, found in association with crippling osteoarthritis. It is also seriously open to doubt how far it is true that the disease ever becomes latent. The case would have to be a very special one to render the operation justifiable. The operation has been performed.

CHLORIDE OF ETHYL.

To the Editors of THE LANCET

SIRS,—I should like to know if in your opinion chloride of ethyl is the best local anesthetic for the extraction of teeth stumps? How should it be used? Is there any danger to apprehend from using it in the mouth? Thanking you in anticipation,

I remain, Sirs, yours sincerely, DENS.

March 24th, 1893

* Chloride of ethyl has been very popular amongst dentists as a local anesthetic since its introduction a year or two ago. It is well to place a piece of lint over the gum before applying it. We have heard of no bad effects following its use.—ED. L.

"PREPARING FOR THE INTERNATIONAL MEDICAL CONGRESS."

SEVERAL correspondents have asked us for suggestions as to books by which a working knowledge of the Italian language on the methods of Lock and Milton, might be obtained. To these correspondents we have already replied but a work has just come under our notice to which we would like to draw our correspondents' attention as affording an excellent means of continuing their studies on the lines referred to. This is the 'Purgatory of Dante, a new translation by Charles Lancelot Shadwell M.A., B.C.L. published by Macmillan and Co., London. The work is described as an experiment in literal verse translation, and contains the Italian text with a translation on the opposite page.

D. T. R.—We are of opinion that as the works were new and the employers a new firm who wrote impartially to A., B. and C. each of the three practitioners was at liberty to make application for the office, and that in doing so he did not lay himself open to the charge of being grasping."

Dr W. H. Hewlett.—Our correspondent is warmly thanked for directing attention to what is evidently a *lapsus oculorum*.

"CANCER PLASTERS"—ERRATUM

To the Editors of THE LANCET

SIRS—In the letter you publish on the above subject in your last issue (March 25th p. 652) there is a misprint which rather misleads. In Case 1 second column fourth line, 'Some ivory plasters' should be 'Some seventeen plasters.' I am Sirs yours faithfully,
County Hospital, Durham, March 25th 1893. SELBY W. PLUMMER.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria park E - Pathologist Salary 100 guineas per annum Apply to the Secretary at the Office, 24 Finsbury-circus E.C.
COUNTY ASYLUM, Rainhill - Assistant Medical Officer (unmarried) Salary to commence at £100 a year, with prospect of an increase at the end of the first year Furnished apartments, board and attendance provided
COUNTY ASYLUMS, Gloucester - Third Assistant Medical Officer Salary £105 per annum, with board, lodging and washing, but no intoxicants
CUMBERLAND INFIRMARY Carlisle. - Assistant House Surgeon, for one year Salary £40 per annum, with board, lodging and washing
DENTAL HOSPITAL OF LONDON, Leicester square - Assistant Anesthetist
EAST LONDON HOSPITAL FOR CHILDREN, Glamis road, Shadwell, E. - House Physician Board and lodging provided
GENERAL INFIRMARY AT GLOUCESTER AND THE GLOUCESTERSHIRE EYE INSTITUTION - House Surgeon Salary £100 per annum, with board, lodging and washing
HASTINGS ST. LEONARDS AND EAST SUSSEX HOSPITAL, Hastings - Honorary Assistant Surgeon
HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton. - House Physicians.
LIVERPOOL STANLEY HOSPITAL. - Assistant Honorary Physician
MILLER HOSPITAL AND ROYAL KENT DISPENSARY Greenwich road S.E. - Junior Resident Medical Officer, for twelve months. Salary £30 per annum with board, attendance and washing
POPULAR AND STEPHEN SICK ASYLUM DISTRICT - Assistant Medical Officer for the Asylum at Bromley, Middlesex E Salary £130 per annum with rations, furnished apartments and washing Apply to the Clerk to the Managers Bromley Middlesex, E
ROTHERHAM HOSPITAL AND DISPENSARY - Assistant House Surgeon, for six months. Rooms, commons and washing provided in the hospital.
ST BARTHOLOMEW'S HOSPITAL, London - Physician
WEST NORFOLK AND LYNN HOSPITAL Lynn - House Surgeon and Secretary Salary £80 per annum, rising to £100

Births, Marriages and Deaths.

BIRTHS

BRYSON - On March 27th, at Hill Lodge, Harrow, the wife of Leonard H Bryson, M.D. of a daughter
CALVERT - On March 25th at Queen Anne street W, the wife of Jas Calvert M.D. of a son
DRAKE BROCKMAN - On March 28th at Ealing the wife of Brigade Surgeon Lieutenant-Colonel E. F. Drake Brockman F.R.C.S. Indian Medical Service of a daughter
HALES - On March 22nd, at Holt, Norfolk, the wife of R. T. Hales, M.D. of a daughter
LEES - On March 19th at Bass House Foregate-street, Chester, the wife of William Lees M.R.C.S. of a son
PERRY - On March 22nd at the Superintendent's House Guys Hospital, the wife of E. C. Perry, M.A. M.D. of a daughter
THOMAS - On March 27th at Swaffham the wife of Augustus William Thomas, L.R.C.P.S. Edin., of a daughter

MARRIAGES

BREESE-LEIGH - On March 25th, at St. Michael's Church Headingley Leeds, Frederick Breeze L.D. Eng. of Kennington park road to Hannah Letitia (Lettie) eldest daughter of Walter T. Leigh, of Brookfield terrace Headingley Leeds
GOODALL-MACKENZIE - On March 25th at Christ Church Barton hill Bristol for the Rev F. Billett brother in law of the bride Edwd Wilberforce Goodhall M.D. Lond to Kate Ellen Mackenzie
WILLIAMS-WOODWARD - On March 21st, at Emmanuel Church, West Dulwich, by the Rev Dr Roe Vicar and the Rev S. P. G. Property, of Fulham G. Chisholm W. Williams M.R.C.S., L.R.C.P., L.S.A. of Dunstons Brockley S.E., to Amy Hannah elder daughter of the late James Woodward, Esq., of Camberwell.

DEATHS

HOPE - On March 27th, at Curzon street, Mayfair, William Hope, M.D.
JONES - On March 24th, at Court House Tonypandy Glamorganshire, Charles John Jones M.R.C.S. E., L.R.C.P. L. and J. P., aged 63
MCDOWALL - On March 20th at the Darham County Hospital suddenly Thomas Henry aged 16 eldest son of J. W. McDowall M.D. Northumberland County Asylum Morpeth
MASTERMAN - On March 20th at York House Stourport, Worcester, George Frederick Cadogan Masterman M.D. aged 60
WEBSTER - On March 20th Thomas Webster, M.R.C.S. and L.M. of Hogarth road Carl's court London.
YATES - On March 26th at Bolton, Peter Yates, M.D., C.M. Edin., aged 51

N.B. - A fee of 5s. is charged for the insertion of Notices of Births, Marriages and Deaths

EDITORIAL NOTICE

It is most important that communications relating to the Editorial business of THE LANCET should be addressed exclusively "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET should be addressed "To the Publisher."

We cannot undertake to return MSS not used.

PUBLISHER'S NOTICE

IN order to facilitate the work of reference to the volumes of THE LANCET, we have arranged in the future to publish duplicate copies of the Index to each half yearly volume in a form in which they may be subsequently filed or bound together.

We have had a large number of duplicate copies of the Index to the last half yearly volume printed, and those of our subscribers who may wish to be supplied with loose copies can obtain the same (without extra charge) on making application to the Publisher of THE LANCET.

RUPTURE OF INTESTINE CAUSED BY A TAPEWORM

In the *New York Medical Journal* for Feb 11th, Dr Dunlap of Donville reports a remarkable and very successful instance of intestinal surgery. He was called to a married lady who was suffering from the symptoms of shock and internal hemorrhage and he diagnosed a ruptured ectopic gestation, and immediately proceeded to open the abdomen. The pelvis was found to be full of recent blood-clot, but the generative organs were perfectly normal. On flushing out the abdomen a long tapeworm floated to the surface and on following it up it was found to protrude from a large ragged opening in the small intestine and the head of the parasite was attached about twelve inches higher up. The opening in the bowel was an inch and a half long and involved about two-thirds of the circumference of the bowel and its edges were ragged and gangrenous. The damaged part of the bowel was excised and the two ends were united by a continuous Lambert suture. The patient recovered. This case is of interest on account of the remarkable cause of the intestinal rupture, but it is still more valuable as another example of successful circular enterorrhaphy by simple means without any special appliances. Only a short time ago circular enterorrhaphy was condemned, and various devices were introduced to accomplish the speedy and safe union of completely-divided intestine. The most recent experience goes to show that the condemnation was too speedy and that the simple suture of the bowel is a really practical procedure.

'KISS THE BOOK SIR.'

To the Editors of THE LANCET

SIRS,—For the guidance of those members of our profession who desire to swear with uplifted hand but are told that they cannot be permitted to do so I beg to submit the law on the subject and to suggest that each medical reader of the following paragraph should cut it out and paste it into his visiting list for ready reference—

Oaths Act 1833

Section 5.—If any person to whom an oath is administered desires to swear with uplifted hand in the form and manner in which an oath is usually administered in Scotland, he shall be permitted so to do and the oath shall be administered to him in such form and manner without further question.

I am, Sirs, yours truly

MUSGRAVE CRAVEN

Kendal, March 21st, 1893.

* We insert our correspondent's letter, although we have repeatedly published Section 5 of the Oaths Act, 1833.—ED L.

THE EFFECT OF CHANGE ON THE JADED LONDONER.

A PRACTITIONER sends us the following account which he has received from a patient who had from overwork and confinement in doors become seriously impaired in health, and whose appetite had completely gone. He gives it as an illustration of the immediate effect of change of environment mode of life meals and society upon the jaded Londoner. In some places this effect is very marked, notably at the sea-side resorts on the east and south coasts. He writes. Struck on former occasions with the effect of complete change, I advised my patient to eat whatever he fancied and asked him to note the items of his diet on a piece of paper. The patient wrote that the following was the dietary of the first day. At eight o'clock I had one boiled egg, two biscuits and one cup of tea served in bed. After an hour's walk along the seashore I returned at ten to breakfast. It consisted of one fish one boiled egg and a rash of bacon, one cup of coffee and a roll and butter, all of which I ate with pleasure. This was followed by a walk along the shore till twelve o'clock, when I had a bottle of stout, two biscuits and a piece of cheese. A brief ride on a bicycle made me wish for something cooling and at one o'clock I had a glass of Scotch whisky with lime juice and ate two bananas. I drove home to dinner, and at half past two I was able to consume the following with much relish. A plate of mock turtle soup, one roll and a glass of sherry, half a chicken, potatoes and cabbage, with one glass of burgundy and a piece of Gorgonzola cheese. I engaged an open boat for the afternoon and at five o'clock returned to a cup of tea and a bath bun. After enjoying myself with pleasant company, I returned to my hotel to partake of a piece of fricasseed rabbit, a piece of cheese and a glass of whisky toddy, before retiring to rest. I was much surprised at my own endurance, and in the evening I experienced a feeling of repose and content to which I had long been a stranger. This account does not include sweets, apples and oranges which were consumed during the day. The improvement wrought by so brief a sojourn is hardly likely to be prolonged but as a restorative many can endorse the writer's experience of change of air.

Iakob.—The cases in which excision would be justifiable are very few if any. The probability of nerve disturbance is so great that failure of perfect bony union might be met with. 'Perfect general health is very rarely if indeed ever, found in association with crippling osteoarthritis. It is also seriously open to doubt how far it is true that the disease ever becomes latent. The case would have to be a very special one to render the operation justifiable. The operation has been performed.

CHLORIDE OF ETHYL

To the Editors of THE LANCET

SIRS—I should like to know if in your opinion chloride of ethyl is the best local anesthetic for the extraction of teeth stumps? How should it be used? Is there any danger to apprehend from using it in the mouth? Thanking you in anticipation,

I remain, Sirs, yours sincerely,

March 24th, 1893

DENS.

* Chloride of ethyl has been very popular amongst dentists as a local anesthetic since its introduction a year or two ago. It is well to place a piece of lint over the gum before applying it. We have heard of no bad effects following its use.—ED L.

'PREPARING FOR THE INTERNATIONAL MEDICAL CONGRESS.'

SEVERAL correspondents have asked us for suggestions as to books by which a working knowledge of the Italian language on the methods of Lock and Milton, might be obtained. To these correspondents we have already replied but a work has just come under our notice to which we would like to draw our correspondents attention as affording an excellent means of continuing their studies on the lines referred to. This is the 'Purgatory' of Dante a new translation by Charles Lancelotti Shadwell, M.A. B.C.L. published by Macmillan and Co., London. The work is described as an experiment in literal verse translation, and contains the Italian text with a translation on the opposite page.

D T R.—We are of opinion that as the works were new and the employers a new firm who wrote impartially to A., B. and C. each of the three practitioners was at liberty to make application for the office, and that in doing so he did not lay himself open to the charge of being grasping.

Dr W H Heulett.—Our correspondent is warmly thanked for directing attention to what is evidently a *lapsus oculorum*.

'CANCER PLASTERS'—ERRATUM.

To the Editors of THE LANCET

SIRS—In the letter you publish on the above subject in your last issue (March 25th p 632) there is a misprint which rather misleads. In Case I, second column fourth line. Some ivy plasters should be 'Some seventeen plasters.' I am Sirs yours faithfully,

During the week marked copies of the following newspapers have been received —*Warrington Guardian, Banbury Telegraph, Lincolnshire Chronicle Lancashire Daily Post, Cambrian (Swansea), Stirling Saturday Observer, Leicester Advertiser, Birkenhead News, Morning Post (Allahabad), Larne Reporter, Madras Times, Truth, Leeds Mercury, Acton Gazette, Llancollen Advertiser, Evening Post (New York), Blackburn Daily Telegraph, Guardian Bristol Mercury, Yorkshire Post Weekly Free Press and Aberdeen Herald, Daily Post shire Mercury, Local Government Chronicle, Liverpool Daily Post, Local Government Journal, Guy's Hospital Gazette, Cambridge Express, Norfolk News, Gloucester Citizen Civil and Military Gazette, Le Temps (Paris), Citizen, Kendal Mercury, Australian Medical Journal, Oban Express, Australian Medical Gazette, Lowestoft Weekly Press, Surrey Mirror, Manx Sun, West Middlesex Standard.*

SUBSCRIPTION

POST FREE TO ANY PART OF THE UNITED KINGDOM.

One Year ——— £1 12 6 | Six Months ——— £0 16 8

TO THE CONTINENT, COLONIES, UNITED

STATES, INDIA, CHINA, AND ALL PLACES

ABROAD ——— One Year 1 14 8

*. In consequence of the new postal arrangements, the Annual Sub-
scription for India, China, and all foreign countries will now be reduced
to £1 14s. 8d., instead of £1 16s. 10d. as formerly

Post Office Orders and Cheques should be addressed to The Publisher,
THE LANCET Office, 425, Strand, London, and crossed "London and
Westminster Bank, St. James's-square."

should be forwarded.

NOTICE.—Advertisers are requested to observe that it is contrary to
the Postal Regulations to receive at Post Office letters addressed to
initials only

An original and novel feature of 'THE LANCET General Advertiser' is a special Index to Advertisements on pages 2 and 4, which not only
affords a ready means of finding any notice, but is in itself an additional advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET

Terms for Serial Insertions may be obtained of the Publisher, to whom all letters relating to Advertisements or Subscriptions should be
addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's Railway Bookstalls throughout the United Kingdom. Advertisements
are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 65, Rue Caumartin, Paris.

REPORT OF THE LANCET COMMISSION

APPOINTED TO INVESTIGATE THE SUBJECT OF THE

ADMINISTRATION OF CHLOROFORM

AND OTHER ANÆSTHETICS

FROM A CLINICAL STANDPOINT

In continuing the publication of the tables of cases which we commenced last week, a few points arise which need passing notice. In the first series of cases which we have described as based upon the list drawn up by the committee of the Royal Medical and Chirurgical Society many fresh cases appear so that our list must not be taken as a mere excerptum of the Transactions of that Society. In the cases which appear in the Transactions many salient facts were not given in the very condensed accounts which the Society published, and these we have been able in some instances to supplement from journals or other published records, thus presenting the cases in a more complete form. We have been unable to append a column containing the name of the administrator and this omission, grave as it may appear, is due to the fact that in a very large number of instances no mention at all is made of the actual administrator or of the experience he may have had in administering the drug. In some cases where mention is made of the person giving the chloroform we find that he was not a medical man at all, thus, in one instance, the master of a workhouse is described as having officiated. In several other cases dentists not holding medical diplomas are reported as having given their patients chloroform. We hope to allude to these cases subsequently. A careful examination of them is peculiarly instructive, as they appear to support the view which some observers have advanced that there is an especial danger of fatalities occurring when the patients are only partially under the influence of chloroform. Again it is noted in most, if not all, of these cases that the patient was placed in a sitting posture in a dentist's chair—a position which some hold to be peculiarly unsuitable to the safe exhibition of chloroform. Many instances occurred in which, whilst comparatively trifling operations were being performed, a fatal accident occurred, and in these, again, we find mention made, or the narrative seems to suggest that the amount of chloroform inhaled was small—probably quite insufficient to ensure complete anaesthesia. The possible occurrence of shock under these conditions requires to be considered. In one case a medical man, previously to a very minor operation, held the towel saturated with chloroform over his face with his own hands—a proceeding we need hardly say, fraught with the utmost danger, especially as in this instance it was found that the stomach was distended with undigested food. A fact worthy of notice is that in comparatively few cases, unless occurring within the precincts of a hospital is any mention made of a second medical man having been present to assist in the administration of the anæsthetic or the performance of the operation. This omission no doubt in some instances is due to force of circumstance, but can hardly be so in all. It would indeed seem as if in some of the cases but few if any, precautions or preparations were made before the chloroform was administered. It certainly would appear that a proportion of these deaths was preventable—that is, in the sense that various obvious dangers were not avoided and that various conditions tending to enhance the danger incurred were overlooked or ignored. Amongst the most conspicuous

are posture, to which we have referred above, in dealing with the dental cases and the above cited instance with others of food given just before the use of the anæsthetic. Yet another reflection occurs when we deal with the chemical purity of the chloroform employed. In some instances actual published statements appeared asserting that the chloroform employed was impure and had undergone partial decomposition giving rise to cough, dyspnoea and finally to suffocation. It is well known that such changes pretty rapidly develop when chloroform is exposed to diffused daylight, especially if kept in a warm room. It is probable that most or all of the chloroform sold by the wholesale makers is sufficiently pure to be free from deleterious matter, and that whatever impurity does appear does so after the chloroform has passed into the hands of the person who administers it.

Another point of great interest occurs in connexion with the evidence afforded by the post-mortem examinations. We published in the first portion of our report descriptions of necropsies in a tabular form, and in the lists which we are now reviewing fuller particulars are presented in Column 8. Unfortunately the examinations are of little value as a guide to what changes, if any, are actually brought about by the chloroform itself, because in by far the majority of instances they were not made until twenty-four hours or even longer after decease. They, however, emphasise the frequency of the association of certain lesions with fatalities under chloroform. In comparing Columns 8 and 9 discrepancies will be detected in that, whilst the examination of the patient's respiratory and circulatory organs during life and before chloroform was given went to show that the patient was organically sound, the necropsy told another tale. There is no doubt that if a preliminary physical examination of a patient is made—and as to the advisability of this step it is beside our present purpose to inquire—it should be carried out as thoroughly and minutely as would be done were the individual to submit himself for a diagnosis upon some malady from which he was suffering. In not a few cases when the patient was described as "healthy," further inquiry elicited the fact that organic disease existed, but the general appearance of the patient was healthy.

Column 7 in which we deal with the symptoms, when considered in conjunction with Column 6 shows that in a large proportion of cases some note—at times fairly full—was kept of the state of respiration and of the pulse. It would seem from these records that it is a common practice amongst surgeons to devote attention to both systems and to adopt resuscitative measures promptly on the appearance of apnoeal phenomena. In many of the cases it will be noted that mention is made of a renewal of the inhalation, but this is not sufficiently specifically stated for us to do more than draw attention to what may be a clue towards finding an explanation of some of the deaths. We shall return both to this point and to the question of the observation of respiration when we consider the cases which we have classed as "untoward cases."

DEATHS UNDER CHLOROFORM
CASES BETWEEN 1860 AND 1891 FROM PUBLISHED RECORDS (*continued*)

1 Reference.	2 Age.	3 Sex.	4 Operation and duration of administration.	5 Method of administration.	6 P or R.	7 Symptoms occurring under anæsthetic.	8 Assigned cause of death.	9 Remarks.
99	38	M	For hemorrhoids with external strangulation of prolapsed rectum.	Napkin. 2 dr		Face somewhat livid, but P and R. good, so operation about to be begun. Turned on right side ceased breathing. P both at wrist and carotids imperceptible face dark livid. Placed on back, head lowered, cold affusions caused four long full aspirations, but no return of circulation. Artificial R. withdrawing tongue and elevating epiglottis.	"From sudden spasmodic contraction of heart, continuing till life extinct, this being effect of CHCl ₃ on ganglionic nervous system." P M Venous congestion of brain, choroid plexus congested	
100		M	For diseased bone in leg (3 minutes)		P	Had not inhaled more than 3 minutes when P ceased and death ensued.	Paralysis of heart. Death attributed largely to effect of fear	Heart and lungs were carefully examined before administration was nervous about taking CHCl ₃ .
101	40	M	Amputation of thigh for inflammation of knee joint.	Towel.	P & R	Operation performed, breathing good, P strong. In 3 or 4 minutes teeth became clenched R. stertorous, 1 small, skin with clammy perspiration. Measures adopted were forcing open jaws drawing out tongue, artificial R. stimulants, but patient died 10 minutes after first alarming symptoms.	P M. All organs healthy but pale from want of blood. Diseased joint examined synovial membrane converted into gelatinous mass. Heads of tibia and fibula completely destroyed and bones roughened.	
102	33	F	Extraction of stumps of teeth.			After 8 or 9 teeth had been removed livid expression came over patient's face and she seemed sinking. All usual means used for resuscitation—such as galvanism, stimulants, artificial R, &c	Death from a state of brain induced by inhalation of chloroform, in reference to which more than usual precautions had been taken	
103	52	F					1 M Disease of heart chloroform."	
104	52	F	For applying nitric acid to wounds of tumours on knee.	Skinner's inhaler 2 dr		Patient died instantly without warning immediately after muscular action. Measures resorted to were artificial R. (Marshall Hall's method, and Sylvester's method) and galvanism. The last caused diaphragm to act twice with 2 inspirations but no further signs of life returned.	? Syncope. No P M allowed.	Patient was suffering from a tumour on each knee the size of an orange, originally inflamed burse.
105	50	M	Castration (3 to 4 minutes)	On lint 15 to 20 drops.	P	After the first dose of 20 drops had been given and another was about to be administered P ceased. Restorative measures instantly resorted to were—Ammonia, electricity Sylvester's method of artificial R., 1 phlebotomy on elbow (from which 1 oz. dark red blood flowed). Meanwhile hypostatic congestion set up along back and sides.	Syncope. P M Fluid black blood from preliminary incision and from vessels of brain. Dura mater adherent to calvaria and pia mater, and arachnoid of opaque white colour. Heart little larger than usual, with little more fat than normal and little fluid blood of dark red colour in chambers. Action of chloroform on weak heart. ? Syncope. P M. Enlarged heart with thin muscular walls "Paralysis of heart" (probably).	
106		M		Handkerchief 2 dr	P.	P suddenly subsided, extreme pallor. Patient was given sherry, and other means adopted.	Action of chloroform on weak heart. ? Syncope. P M. Enlarged heart with thin muscular walls "Paralysis of heart" (probably).	Nothing before administration to contra-indicate use of chloroform.
107	30	M	Amputation of portion of hand.		P & R	After 6 inspirations breathing became difficult and stertorous. P ceased. Artificial R and other means tried, but death shortly took place.		
108	40	M	Reduction of dislocation of head of humerus	Sponge.		Immediately the dislocation was reduced face became livid and death took place. All means employed for resuscitation.	? Asphyxia. Patient was reported by his physician to have died of apoplexy. ? Syncope.	
109	12	M	Reduction of dislocation of hip (20 minutes)	Handkerchief. 2 dr	P	During operation P failed and patient died at once		

DEATHS UNDER CHLOROFORM
CASES BETWEEN 1860 AND 1891 FROM PUBLISHED RECORDS (*continued*)

1	2	3	4	5	6	7	8	9
Incidence.	Age	Sex	Operation and duration of administration.	Method of administration.	P or R	Symptoms occurring under anæsthetic.	Assigned cause of death.	Remarks
110		F	Extraction of teeth.		R.	When extraction of teeth over, patient stopped breathing was laid on floor and artificial R. tried with no avail.	? Syncope	Sitting posture. Had already taken CHCl_3 twice at the same sitting
111			Amputation of leg			Patient died about a minute after CHCl_3 had been given.		
112		F	Extraction of teeth.		P	"After extraction of teeth patient went into spasm or convulsion and limbs became rigid. Was placed on lounge reclining, whole muscular system relaxed. P ceased and after gasping a few times suddenly died. Diligent but unsuccessful attempts at resuscitation.	? "Nervous shock or CHCl_3 or both combined.	Sitting posture. Patient was advised to do without CHCl_3 but insisted upon CHCl_3 or other being given.
113	35	M	Amputation of finger	Quantity small.			P M Heart: right auricle fatty? Spleen ruptured and blood in peritoneum.	Patient very nervous. Usual precautions taken, and heart found normal but if fatty degeneration as stated by medical witness careful examination would have detected it. Death might have happened from impure CHCl_3 . The reporter insists that it would have been discovered whether impure CHCl_3 caused the death, by application of the acid test.
114		F	For relief of prolapsus uteri.				P M Nil, except slightly flabby heart	Death might have happened from impure CHCl_3 . The reporter insists that it could have been discovered whether impure CHCl_3 caused the death, by application of the acid test.
115							P M Heart diseased but no particulars given.	
116	?	?		Lint cone.	P	P stopped suddenly and all efforts to restore animation unavailing	P M appearances nil except large and flabby heart	CHCl_3 pure.
117	32	F	Removal of malignant fungoid growths from gums and lower jaw by galvanic cautery (15 minutes)	Skinner's flannel mask.	P	On the third introduction of the heated wire patient instantaneously expired. Battery at work applied to chest mouth to mouth insufflation and Silvester's method tried with no effect.	Syncope probably secondary to mechanical interference with respiration. P M Large goitre on neck bloody mucus o cupying larynx and trachea heart cavities all empty lungs pallid and emphysematous.	Anæmic.
118		M	For caries of ankle joint preparing for amputation	Folded towel	P & R.	One minute after first inspiration convulsive movement of extremities CHCl_3 removed, head declined. After 4 or 5 convulsive inspirations ceased breathing face livid pupils dilated; eyes and jaws open heart's action maintained for 40 minutes.	? Syncope.	
119		M	For hæmorrhoids.			When everything ready for operation patient died.	? Syncope P.M. Heart exceedingly fatty Liver far advanced in cirrhosis. Spleen with multiple abscesses	Had been suffering from variety of symptoms referable to intemperate habits
120		M	On wrist.					Had on two recent occasions undergone same treatment.

DEATHS UNDER CHLOROFORM
CASES BETWEEN 1860 AND 1891 FROM PUBLISHED RECORDS (*continued*)

1 Reference.	2 Age.	3 Sex.	4 Operation and duration of administration.	5 Method of administration.	6 P or R.	7 Symptoms occurring under anæsthetic.	8 Assigned cause of death.	9 Remarks.
121	30	M	For diseased bone	On lint. 1 dr		When only partially under influence of anæsthetic, death suddenly took place. Every means for resuscitation used with out avail. Tongue drawn forward artificial R galvanic battery over heart and neck and diaphragm. Artificial R for $\frac{1}{2}$ hour. Right jugular vein also opened.	? Syncope P M Degeneration of muscular fibre of heart, endocarditis shown by roughening of mitral and aortic valves. General congestion of viscera.	No symptoms during life of cardiac disease or clue to cause of heart disease.
122	21	M	Reduction of dislocated hip (20 minutes)	2 dr	P	P failed and patient died immediately	Syncope.	
123	1	F	Extraction of tooth					Sitting posture.
124	14	M	For necrosis of tibia.		P & R	Operation was commenced when patient was seized with vomiting. Breathing ceased and P became imperceptible. Usual measures taken for resuscitation.	Syncope. P M appearances not except enlarged liver	
125	26	M	Insertion of drainage tube in thigh for disease of neck of femur	Oil lint. 1 dr	P & P	R ceased. Face pale at first and shortly became livid. Artificial R (Silvester's method), tongue pulled forward, and battery	Syncope P M Lungs dark red and large bronchial tubes full of thin frothy fluid. No clot in pulmonary arteries. Heart large with only shred of decolourised clot in left ventricle. Wall of left ventricle thicker than natural and cavities generally large. Heart 14oz. Bits of wall of left ventricle showed granular degeneration. Striae obliterated. Endocarditis on aortic valves.	The commencing fatal degeneration of heart sufficient to account for chloroform being fatal.
126	68	M	Amputation of foot.	1 dr (about).	P	Suddenly became rigid and P stopped. Every exertion made for restoration artificial R for $\frac{1}{2}$ hour with no avail.	? Syncope.	
127	42	M	To quiet tetanic spasms after fracture of both legs		P	After few inspirations I ceased. Artificial R and drawing out tongue resorted to. Soon circulation and R restored but after being put to bed R. ceased and life became extinct.	? Syncope.	
128	22	F	Ovariectomy	On towel		Patient vomited suddenly and profusely. Immediately eyes opened pupils proter naturally dilated face became pallid and R affected. Measures adopted were Artificial R and pulling forward of tongue. Deep spontaneous R several times in succession but death followed on a second collapse.	? Inhalation of chloroform causing syncope but in this case great doubt as to whether syncope was not caused by operation itself (see L 25 Feb 1870, pp 297-299). P M No diseased conditions in head or chest or elsewhere. Ovarian tumour free from peritoneal adhesions.	Patient thin and emaciated.
129	1	F	For opening of whitlow	3 dr				
130		F	Removal of epithelioma of tongue	(1) Coil of paper (2) napkin. 2 dr		Suddenly fainted, and despite all efforts made for a long time never breathed again.	Direct poisoning of nervous centres by <chem>CHCl3</chem> .	
131	6	F	For convergent strabismus of left eye.			Operation performed while patient not fully under <chem>CHCl3</chem> . Patient was restless, shortly after operation ceased breathing. All efforts to restore R futile.		
132		M	Amputation of forearm.		P	P became weak. R ceased, and after one or two respiratory efforts patient died.	P M Blood very fluid. Right auricle and right ventricle enormously distended. Advanced fatty degeneration of heart.	

DEATHS UNDER CHLOROFORM.

CASES BETWEEN 1860 AND 1891 FROM PUBLISHED RECORDS (*continued*)

1	2	3	4	5	6	7	8	9
No.	Forcee	Age	Operation and duration of administration.	Method of administration.	P or R.	Symptoms occurring under anæsthetic.	Assigned cause of death.	Remarks.
2		31	Amputation of left leg crushed by railway engine.		P	Anæsthesia induced almost instantly P became slow and irregular breathing irregular Symptoms improving operation was performed. Again P failed with spasmodic gasping breathing Artificial R. tried, with no effect.		Patient intoxicated when leg crushed, but being a stranger his habits of life were not known.
34		F	Reduction of dislocated shoulder	2 dr		Took CHCl_3 well, but ceased to breathe soon after	Organic disease of heart.	"Was a stout woman with good colour"
35	24	F	Foreble extension of knee.		P & R.	As symptoms of asphyxia appeared the operation could not be continued. Artificial R. restored breathing for 1 minute but it again became irregular and I became imperceptible. Tracheotomy venesection and electropuncture tried with no effect.	? Syncope or asphyxia. P.M. Small vegetations on valves of heart. It is to be noted that P became imperceptible before R. stopped.	
36			Fistula in ano.					
140		F			P & P		Syncope.	Had been given CHCl_3 a week before, but it did not take effect.
141		M	Amputation of thigh.	Clover's apparatus.	P	Two minutes after cessation of giving anæsthetic patient became faint and sick heart ceased to beat	Death not directly due to administration of chloroform, but rather to shock acting on feeble heart in very unhealthy subject	Patient strumous and anæmic Chloroform given with greatest care and stimulants given before its administration.
145		F	Extraction of 12 teeth.	Napkin.		After extraction of first 4 teeth patient became partially sensible so small doses more given at intervals till all extracted. While reclining or vomiting patient seemed to strangle and suddenly expired. Was placed horizontally and artificial R. kept up $\frac{1}{2}$ hour	Asthenia of heart. I.M. appearances nil	Had taken CHCl_3 well two years previously Sitting posture.
149		M	Sounding for stone.	Clover's inhaler	P & R	Some terror which passed off when put in position. When sound introduced R. suddenly stopped during inspiration, and I could not be felt. Face became dusky pale. Artificial R. for 20 minutes and galvanism over præcordia tried. Pupils not noticed.	? Syncope P.M. Heart moderate amount of dark blood in right side little in left organ loaded with fat which penetrated deeply into substance walls pale and soft much interstitial fat and fatty degeneration of fibres Some atheroma of aorta. Kidneys congested and albuminoid. Bladder contained pyramidal stone impacted in neck. P.M. "Poisoned by chloroform." Paralysis of heart.	Had stricture of urethra and stone in bladder Was unable to retain urine for more than five minutes and could get no sleep from pain.
150	34	M	Fracture of leg					
151		M	Removal of cystic tumour over left eye.		P	Operation nearly completed when patient threw back head, neck became stiff, and he gasped. Efforts made to restore him for $\frac{1}{2}$ hour with no effect.		
152	34	M	Amputation of finger (3 or 4 minutes).	Lint.		After inhaling the drug 3 or 4 minutes he expired.		"Death from tetanus, accelerated by chloroform."
153	40	M	Surgical examination.			Died suddenly		
154	5	M	Fistula in ano		R.	When the operation had been completed, patient placed on his back. Breathing ceased and he became livid in face. Heart continued beating though feebly After artificial R. had been employed a few minutes he breathed a few seconds, and then breathing and P ceased altogether Artificial R. for 40 minutes without effect.	Inhalation of chloroform. Failure of R. soon followed by that of heart. P.M. Heart 14 oz., left ventricle full of dark fluid blood, its walls pale and flaccid and covered with	

DEATHS UNDER CHLOROFORM
CASES BETWEEN 1860 AND 1891 FROM PUBLISHED RECORDS (*continued*)

1 Reference	2 Age	3 Sex	4 Operation and duration of administration	5 Method of administration.	6 P or R	7 Symptoms occurring under anæsthetic	8 Assigned cause of death	9 Remarks
155	36	F	Fractured jaw				only a thin layer of fat. Mitral orifice admitted tips of four fingers. Muscular fibres of heart with abundance of fat globules. Lungs congested, pulmonary artery full of blood. Spleen large and soft.	
156			For dislocated humerus.				P M 'Chloroform. Fatty heart.'	Heart and lungs carefully examined before operation.
157	2	M	Iridectomy	In flannel cone $\frac{1}{2}$ dr	P & P	After a drachm of CHCl_3 had been given operation commenced, but as pain was observed 20 minutes more given. Operation completed when suddenly stertorous breathing began. Lips and face turned blue and sterno mastoids became contracted. Cold water and artificial R (Silvester's method) R returned. But lividity came back and veins of neck and temple were swollen. Artificial R and battery and frictions maintained for 1 hour, but the heart ceased to beat.	Inhalation of chloroform causing direct paralysis of heart. No 1 M.	
158	1		Amputation of foot		R.	R ceased. Died suddenly. No stertor or gasping.	'Paralysis of heart.' P M Fatty degeneration of heart. Not enough to account for death.	
159	11	M	Iridectomy and removal of lens	2 dr (about)	P & R	While the dressing was being applied the lad made several deep inspirations and then ceased breathing. I could not be felt. Other pupil much dilated. Artificial R and other means succeeded in temporarily restoring the P and colour and a few respiratory movements, but further collapse set in and after $\frac{1}{2}$ hour of further effort hope was abandoned.	P M failed to exhibit any peculiarity.	
160	31	M	For reduction of dislocation of shoulder joint	$\frac{1}{2}$ oz. (about)	P	After 1 ounce CHCl_3 given more CHCl_3 sent for, patient meanwhile recovering. After second dose from second bottle spasm and cessation of heart's action came on—then sudden death.	'Death from the effects of chloroform administered with out proper degree of care (Verdict of Coroner's Jury.) M T & G correctly claimed that this was 'monstrous,' as CHCl_3 accidents happened with the most experienced surgeons.	
161		F	Extraction of tooth			Died 5 minutes after extraction of tooth.		Was in perfect health.
162		F	Extraction of tooth		R.	Difficulty of breathing came on about $\frac{1}{2}$ hour after operation and no restorative measures were of avail. It was significant that the blood coagulated almost immediately after operation, and that there was no hæmorrhage.		Sitting posture. 'If taken (CHCl_3) was twice before.
163		M	For perineal abscesses and fistula.	Lint cone.	P & R	More violent than usual during second stage. CHCl_3 discontinued and operation begun. Was turned on left side when suddenly breathing and I ceased. Tongue held and artificial R. cold water douche application of ammonia and other methods tried. Of some avail for short time but breathing ceased.	Paralysis of heart. 1 M. All organs healthy, but immense amount of fat.	
164		M	Amputation of leg	On lint 3 dr		Before operation commenced, and after inhaling the CHCl_3 , he became excited with spasm and rigidity. I became rapid and feeble, but heart still beat. Galvanism from neck to diaphragm and artificial R practised. Consciousness partially restored. R. feebly re-established and P returned at wrist, was able to swallow a little brandy, but died soon after.	Sank through depression of vital power caused by hæmorrhage and injury.	

DEATHS UNDER CHLOROFORM
CASES BETWEEN 1860 AND 1891 FROM PUBLISHED RECORDS (*continued*)

1 Reference.	2 Age.	3 Sex.	4 Operation and duration of administration.	5 Method of administration.	6 P or R.	7 Symptoms occurring under anæsthetic.	8 Assigned cause of death.	9 Remarks.
65		M	For forcible extension of ankylosed knee joint.	1½ dr		Unconsciousness supervened and patient died in about ½ hour		Had been given CHCl ₃ several times for over a week preceding operation.
66		M	For reduction of dislocation of right shoulder		P	While dislocation was being reduced by means of pulleys patient suddenly ceased to breathe. Water dashed in face tongue pulled forward. Artificial R., and galvanic battery applied. 3 or 4 faint respirations obtained, but heart did not beat again.	Syncope. P.M. Heart flabby, in folds, not contracted muscular fibres fatty, veins and liver much congested.	
67	50	M	For putting leg with dislocated tibia and fractured fibula in swing apparatus (4 minutes). Amputation of ulcerated leg	Handkerchief. Less than 1½ dr	P & R	Limbs were about to be raised from splint when dangerous symptoms appeared. Artificial R. for 40 minutes restored heart's action and breathing but both soon ceased, and no efforts to arouse them availed.		
68	49	F			P	Just before insensibility came on patient became suddenly livid. P. ceased. 1 or 2 gasps. Artificial P., cold water sprinkling and flogging and small quantity of blood drawn from jugular vein. 1 or 2 gasps probably death throes. Retinal veins much distended.	From blood being unable to pass through lungs. P.M. Lungs dark red very little blood escaped from tissues when pressed. Patches of collapse in both. Heart right side healthy largely empty because veins of neck had been divided and blood had escaped. Left ventricle with very little blood, its muscle pale and soft, showing fatty degeneration but no yellow lines across muscle.	Had been suffering from syphilitic ulceration of leg. Had taken CHCl ₃ well a week previously, but vomited for 3 days afterwards and had 2 rigors. Had to be given food by enema.
169 170	39	F	Extraction of 8 teeth.	Napkin.	P	Anæsthesia partial when tooth extracted patient screamed loudly fainted was laid on lounge. P. and heart action ceased, and R. at length failed. Measures resorted to were Artificial R. electricity cold water and stimulating enema.	? Syncope No P.M. reported	Sitting posture Of delicate health very nervous mother of 8 or 9 children. Had taken CHCl ₃ in all her labours except the last and the same for teeth extraction on 3 different occasions previously to fatal dose. Opinion expressed that if CHCl ₃ had been pushed to insensibility the case would have ended differently.
171		F	Extraction of tooth.	Cone made from handkerchief. 3 dr	P	Deathly pallor came over countenance. Heart ceased. Artificial R. by mouth to mouth inflation for 1 hour. Anæsthesia was only partial.	Syncope.	Sitting posture Nervous delicate no organic disease.
172		F			P & R	Had fair P. and regular R. up to very instant when both ceased.		
173		F				Died on 6th day from vomiting caused by first inhalation of CHCl ₃ .		
174 175 176 177						In a few of these cases death was gradual.		
184		M	For wound left by amputation dressing	Less than ½ oz.				The first death after a long and frequent use of CHCl ₃ . Had taken CHCl ₃ twice latterly—viz., 3 days before and 7 the day before his death.

DEATHS UNDER CHLOROFORM
CASES BETWEEN 1860 AND 1891 FROM PUBLISHED RECORDS (*continued*)

1 Reference	2 Age	3 Sex	4 Operation and duration of administration	5 Method of administration	6 P or R	7 Symptoms occurring under anæsthetic.	8 Assigned cause of death.	9 Remarks
185	8	M	Dressing external burn on dorsal and lumbar regions		R.	After inhalation had been discontinued breathing had ceased. Measures employed were Artificial R. (Silvester's method) and galvanism of diaphragm through phrenic nerve. A few gasps accompanied the galvanism at first. Artificial R continued for $\frac{3}{4}$ hour.	P Failure of respiration. P M Blood dark coloured. Small clot in right ventricle, left contracted. Left lung firmly adherent to upper lobe of pleural costa, in lower lobe lobular collapse and some emphysema, lining membrane of trachea congested and swollen in minute bronchi rusty coloured frothy mucus.	The wound would heal and general health of patient was bad.
186	45	M	Amputation of middle finger for necrosis	3 dr	P & R	Patient hardly under influence of drug when he died suddenly. No alteration noted in breathing till face became pale, and heart's action almost immediately was arrested. Measures employed were Artificial R and galvanism.	Syncope P M Heart fatty	
187	37	M	For radical cure of hernia	Towel	P & T	P and breathing suddenly ceased. Measures taken. Trunk bent and neck laid straight. Tongue drawn out. Artificial R (Silvester's method) ammonia to nostrils. Galvanism cold affusions. Vein on arm and jugular vein opened. Treatment for $\frac{3}{4}$ hour. No return of life.	Mixed causes—CHCl ₃ inhalation dread of operation diseased condition of heart. P M Heart walls slightly flaccid. Blood thin and frothy. Walls of left ventricle and septum cordis fatty. Lungs healthy, but deeply loaded with dark fluid blood. Kidneys partially fatty. (<i>B M J</i> 1871 ii p 130). Much blood on right of heart compared with quantity on left. Contra indicates death from gradual asphyxia.	Moderately said to be intemperate.
188	13	M	On eye for squint			When operation completed and patient was recovering from effects of drug he tried to vomit, while so doing he made a deep inspiration which forced back the rising matter and caused suffocation.	Asphyxia	Patient taken to hospital for treatment of an internal disease.
189	34	M	For reduction of fragments of fractured leg	Rag	P	Anæsthesia was incomplete; operation unsuccessful. P ceased beating, usual methods tried with no effect.	From shock to dilated heart. P M Fatty degeneration of liver and kidneys. Brain softened. Heart flabby and much dilated.	Powerful man; seemed intemperate but no trace of alcohol in stomach.
190	33	M	Amputation of first and second toes of left foot					
191				Not more than 1 dr used				
192	48	F	On knee.	Less than 1 dr used				
193	31	F	Extraction of tooth	$\frac{1}{2}$ oz used				
194			For dislocation of elbow					
195		M	Amputation of crushed toe.		P	Almost immediately became violent. P weak and then ceased. Operation had not commenced before fatal symptoms occurred. Galvanic battery applied.	† Syncope.	
196	46	F		1 dr		After one drachm had been used signs of depression began to develop themselves and death occurred.	Syncope.	
197	40	M	On diseased elbow	Less than 1 dr		Died after taking one or two inhalations of a drachm of CHCl ₃ which had been poured on a sponge at least two or three minutes before.		

Sitting posture.

DEATHS UNDER CHLOROFORM
CASES BETWEEN 1860 AND 1891 FROM PUBLISHED RECORDS (*continued*)

1	2	3	4	5	6	7	8	9
Age of patient	Sex	Operation and duration of administration.	Method of administration.	P or R	Symptoms occurring under anæsthetic.	Assigned cause of death.	Remarks.	
34	M	Removal of tumour at edge of sterno-mastoid.		P	Complete resolution was produced, and the first incision had hardly been made when the patient was found to be colourless and without P or sounds of the heart. In spite of all efforts he died.	P M A small vein leading into the external jugular was found to have been obliquely opened. The jugular contained a long clot segmented by some bubbles of air. Other bubbles existed in the mediastinal and post-cardiac veins. The right ventricle contained a notable quantity of air, and some small ecchymoses were the only things remarkable to be observed in the lungs.	Patient had successfully taken chloroform 6 weeks previously	
30	F	For iridectomy for artificial pupil.	Inhaler with lint 3 drs.	P	Violent struggle began when P quickened and then became imperceptible. Face changed from crimson to livid purple. Patient was rolled on to left side and back again. R did not stop but became shallower. I aided by artificial I kept up 20 minutes. Interrupted magnetic current applied over phrenic nerve and enema of brandy and cold water given. Action of heart not restored. Acupuncture between fifth and sixth ribs also tried.	Paralysis of fatty heart. P M Anterior surface of heart covered with layer of fat. Muscular walls thin, pale soft, flabby. Cavities dilated. Right containing fluid blood, left empty. Lungs engorged with dark blood.		
40	F	For ovariectomy.		P & R.	Breathing laboured. Face livid. P failed. Effort to cough with discharge of frothy bloody mucus. Measures resorted to were: Drawing out tongue and artificial R (Silvester's method). These failing it was found that metal plate with false teeth was impacted in the larynx. This was extracted and artificial P continued 40 minutes. Some gasps, but heart failed.	Asphyxia—secondary heart failure. P M Heart thin. Walls and flabby. Right ventricle dilated containing small quantity of fluid blood. Mitral and aortic valves slightly altered by deposit of no fatty degeneration. Lungs healthy. Abdomen encephaloid cancer of peritoneum with ovarian cancer. ? Syncope.		
40	M	Removal of lenses of eyes.	Towel. More than 1 dr.	P	Jerked head off pillow. On being raised, breathing became interrupted and heart's action ceased. Measures resorted to were: Pulling forward tongue, cold water affusion, galvanism to phrenic nerve by Störer's battery. Artificial R for ½ hour. Result, only a few shallow inspirations.	P M Body well nourished. Heart hypertrophied and fatty. Right cavities gorged with blood. No valvular lesions. Lungs emphysematous. ? Syncope. P M Extensive fatty disease of heart.	Thickset met with injury through explosion of blasting powder. Had taken CHCl ₃ once before for operation on eyes.	
30	M	For phagedenic sore.		P	Before patient fully under P ceased. All efforts including galvanism and artificial R of no avail.			
30	F			P & R	P and breathing ceased suddenly after a few stertorous Rs. Usual means resorted to including galvanism which produced some convulsive efforts of the respiratory muscles but animation not restored.			
30	M		1 dr.	P & R.	After short inhalation a few convulsive Ps. and then sudden stoppage of heart's action and breathing. Galvanism, artificial R, and tracheotomy tried without effect. Expired 2 minutes after administration.	Paralysis of heart.		
30	M	On jaw bone.				Paralysis of heart.		
30	M	On hip joint by galvanocautery.			Breathing became stertorous. Tracheotomy instantly performed with other measures but all of no avail.			
30	F	Amputation of thigh.			Patient died on table before operation had commenced.			
30	F	Repair of a bitten-off nose.					Strong and healthy looking	

DEATHS UNDER CHLOROFORM
CASES BETWEEN 1860 AND 1891 FROM PUBLISHED RECORDS (*continued*)

1 Reference.	2 Age.	3 Sex.	4 Operation and duration of administration	5 Method of administration	6 P or F	7 Symptoms occurring under anæsthetic	8 Assigned cause of death.	9 Remarks.
209	24	M	On eye.		P	Became apparently unconscious so that inhaler was being removed, but on showing signs of sensibility it was readjusted. A change seen and heart soon ceased acting. Measures taken to restore animation but without avail.	"Chloroform Meningeal apoplexy" P.M. ? Syncope.	Had taken CHCl_3 for similar operation previously.
210	16	F						
211-214								
215	70	F	Reduction of fractured leg	Small quantity		Patient quickly succumbed to influence of CHCl_3 . Death ensuing when very little had been used.	"We are not aware that any necropsy was made or inquest held.	
216	34	M	Examination of inflamed foot and leg	3 dr	P	P failed, sighing pallor and some lividity. Measures adopted were Artificial R. (Silvester's method) galvanism to heart friction and brandy enemata, abandoned after 3 hours. Operation was being proceeded with when P failed.	Syncope P.M. Lungs and pleurae healthy, lungs apparently, but not really, congested. Heart pericardium healthy, left ventricle neither firmly contracted nor perfectly flaccid, with no excess of blood; muscular fibres somewhat degenerated. Stomach extravasation of blood at cesophageal and Liver large, palish red. Kidneys healthy, large, and venously congested.	Hard drinker. To somewhat extent fairly developed body fairly well nourished. Had taken food for 24 hours before administration of CHCl_3 , but had some beer about hour beforehand.
217		M	Amputation for compound comminuted fracture of left leg	3 dr 10 min.		Vomited twice during induction of anæsthesia. During operation face became livid, tongue was thrust between the teeth and R ceased which was restored on removal of tongue by forceps. To complete operation little more CHCl_3 given (10 minims) which was inhaled for few seconds. Ten minutes after removal of mask R shallow and infrequent, then patient became livid, teeth fixed, and R ceased entirely. Galvanism and artificial R used with no effect.	P.M. Heart pale and empty; mitral valve thickened, some atheromatous deposit in aorta; striae of muscular fibre distinct. Lungs congested.	
218	57	F	Removal of tumour from right breast.	1 dr	P	P suddenly stopped. Breathing became short and shallow, then ceased, face livid, pupils slightly contracted. Measures adopted were Throwing open window, cold affusions, drawing out tongue with forceps, artificial R (Silvester's method); but all useless.	? Syncope. No P.M.	Of active habits, temperate, and in good general health.
219		F	Extraction of teeth			Patient became faint and in spite of every effort to revive her died in a few moments.	Syncope	Sitting posture.
220	49	M	Resetting of broken leg.		P	Before leg could be reset heart suddenly stopped. Usual means, including artificial R, resorted to with no effect.	Disease of heart 1 M Heart and lungs diseased.	Intemperate. Leg had already been set, but patient displaced it in fit of delirium. Was very violent and was suffering from spasms till the CHCl_3 was given.
221	28	M	Amputation of thumb	Napkin.		In a few minutes after administration patient began to struggle a little. Face became suffused, eyes seen to turn up and jerk. Tongue drawn forward. Breathed very heavily for 10 or 15 minutes. After this consciousness never regained. Galvanic battery sent for, none at hand.	? From rupture of blood vessel on brain. "There would probably be some disease of the kidneys." No P.M. reported, or 1 M appearances detailed.	Patient was willing to have operation done without anæsthesia. No second medical man in attendance till just before patient died.
222	35	M	Removal of necrosed bone or amputation of leg, at thigh (15 minutes)		P	Had inhaled CHCl_3 for about 5 minutes, when signs of distress came on and violent struggles to push inhaler from mouth then sudden cessation of heart's action, sudden gasping for breath, brief struggle—death. Measures resorted to were Artificial R. and galvanic battery.	? Syncope.	Health had failed very much from diseased leg and amputation was held out as only likely remedy.

DEATHS UNDER CHLOROFORM
CASES BETWEEN 1890 AND 1891 FROM PUBLISHED RECORDS (*continued*)

1	2	3	4	5	6	7	8	9
Reference	Age	Sex	Operation and duration of administration.	Method of administration.	P or R.	Symptoms occurring under anæsthetic.	Assigned cause of death.	Remarks.
23	42	M	For diseased elbow			Died after taking 1 or 2 inhalations of 1 drachm of CHCl_3 .	Sudden syncope.	
24	51	M	Reduction of Pott's fracture (2 minutes).	Sponge. $1\frac{1}{2}$ dr	P	Breathing became very full and slow not stertorous; no P no heart beat pupils dilated. Measures resorted to were Wet towel, opening jugular vein, application of magnetic electricity to cardiac region and artificial R. for 20 minutes. No return of P but several respiratory attempts.	Syncope. P.M. Lungs adherent by old adhesions emphysema along anterior border and apices of both. Heart small, right ventricle dilated and with auricles full of black blood walls of right cavities thin left ventricle contracted and empty coronary arteries slightlv atheromatous excess of fat on surface of heart. Liver large and in early fatty state	Had been drinking excessively for six weeks before injury.
25	30	M	For injuries to foot.		P	Became violent. P weak, then ceased. Galvanic battery applied, to no purpose.	From overdose of CHCl_3 causing paralysis of heart. No I.M.	Was not examined prior to administration of CHCl_3 . Student had charge of P. An action was brought by patient's widow against the medical men. Finding—for the defendants.
26	40	M	Examination of necrosis of right humerus.	1 or 2 dr	P	Examination was concluded, and in recovering consciousness patient vomited greenish fluid. P hitherto good, suddenly stopped, pupils dilated l. impeded. Measures tried were Artificial R. and galvanism for $1\frac{1}{2}$ hour	Syncope during recovery from CHCl_3 . P.M. Some parts of heart and kidney put aside for examination, but viscera generally healthy	Was the subject of fever from simultaneous necrosis of right humerus left thigh, right tibia and metatarsal bone 4 months previously
27	40	M	Forcible dilatation of sphincter in fissure of anus.	On two small linen compresses in metal cone with 2 air holes.		Patient did not take CHCl_3 well it was therefore given slowly. After dilatation was accomplished, patient showed signs of feeling pain. R became noisy. Chest struck with palm of hand. At this moment eyes were wide open, immovable without expression, breathing ceased and face was cyanosed. Artificial R. (Silvester's method) practised, the air entered left chest but the eye glazed and P ceased. Artificial R. also performed by introducing sound into larynx but former method again resorted to. Battery applied to sides of chest and to epigastrium and also to base of neck. Muscular contractions obtained which gradually diminished and then ceased.	? P.M. Made following day Heart engorged with blood, especially right auricle which was almost as large as the hist. Walls intact valves healthy Blood in cardiac cavities fluid and black without clots. Left lung two tubercles at apex as large as a nut with softened interior at top of lower lobe of same lung large tubercle around which there was slight hæmorrhage.	Patient of good constitution and robust appearance.
28		F	Extraction of tooth.					Sitting posture.
29	16	M	Extraction of tooth.	Napkin.		Artery flickered pallor. Measures adopted were Inversion pulling forward tongue application of ammonia to nostrils cold douche—result of these several inspirations after which breathing ceased. Artificial R. (Marshall Hall's method) and inflation of lungs by bellows unsuccessful in restoring heart's action.	No P.M.	Sitting posture. Patient was suspected to be suffering from some heart trouble.
30			Trivial.			Every means was applied to restore animation without avail.		Patient was young and robust.

DEATHS UNDER CHLOROFORM
CASES BETWEEN 1860 AND 1891 FROM PUBLISHED RECORDS (*continued*)

1	2	3	4	5	6	7	8	9
Ref. source	Age	Sex	Operation and duration of administration	Method of administration	P or R	Symptoms occurring under anæsthetic.	Assigned cause of death	Remarks.
231	60	M	Introduction of catheter owing to rupture of perineum (more than 7 minutes which was duration of 2nd administration)	Clover's apparatus	P	7 minutes after second administration commenced, P flickered and stopped. Restorative measures of no avail. Measures taken were Artificial R. (Silvester's method) for $\frac{1}{2}$ hour, galvanism to phrenic nerve and diaphragm, friction to extremities.	Syncopal. Lungs deeply congested. Right side of heart flaccid and full of fluid blood left side empty and contracted. Arteries in brain and throughout body atheromatous. Blood infiltrated into cellular tissue of perineum and scrotum.	Patient an insane criminal.
232	45	F	Putting fractured arm upon splint and reduction of dislocation of radius.	2 dr	P & R	Violent struggling at first, but after the second draught was given the patient ceased struggling and operation had begun, when patient's face was noticed to be livid pupils dilated. L and R ceased. Patient was laid on floor tongue drawn out with forceps. Galvanic battery applied to phrenic nerve and diaphragm. Valsalva in arm opened and artificial R. performed for $\frac{1}{2}$ hour, but the patient did not respond.		Patient not noted for sobriety.
233	22	F	Tracheotomy				P. M. 'Death by chloroform'	Was suffering from phthisis and tubercular laryngitis.
234		M	Amputation of leg and part of thigh for fracture in both.		P	In the middle of the operation which was very protracted patient began to struggle and became conscious. More CHCl_3 given at once P gave way, patient gasped and was dying. Measures taken were Admission of cold air drawing forward tongue with forceps, attempt at artificial L (Silvester's method)—these measures too late.	Syncopal. Although death was due immediately to CHCl_3 everything had happened previously that could hasten it (1) Patient had suffered injury in coal mine which caused most serious fractures (2) Six hours had elapsed between accident and operation (3) He was carried four or five miles on stretcher, over bad road, in wet clothes, losing much blood and suffering great pain. Case not recorded at the time, because it was generally thought that the injuries caused death, and not the CHCl_3 .	The medical man recording this case insists on the necessity of providing proper room and beds at all large works where accidents so often occur which would double the chance of recovery, even when anæsthetics with their necessary risk have to be given for an operation.
235		M	For injury received in mine.					Patient an injured minor. Delay and loss of blood had taken place.
236			For strangulated hernia.					
237	30	M	Removal of diseased tibia after compound comminuted fracture of both bones of right leg (1 minute)	Int. 1 dr	P	Patient went under easily, and as first incision was made P suddenly failed and stertorous breathing ensued. Cold water was dashed on face. Ammonia applied to nostrils. This roused him for about a minute and the R became easy, when syncope again occurred from which he did not rally. Means employed Ammonia to nostrils turpentine stupes to heart, artificial R. (Silvester's method) galvanic current to respiratory muscles, tongue drawn forward.	P. M. Lungs anteriorly natural posteriorly portions were infarcted. Trachea and bronchial tubes were infarcted. Heart slightly larger than natural. Muscular tissue somewhat flabby. In right ventricle there was a small patch of organised lymph about size of four penny piece. Liver spleen and kidneys healthy. There was an unusual amount of fat in the abdomen.	A strong muscular soldier. General health good.

Reference	Age	Sex	Operation and duration of administration	Method of administration.	P or R.	Symptoms occurring under anæsthetic.	Assigned cause of death.	Remarks.
238		M	On machinery wound of finger			Before full narcosis was established, patient was seized with convulsions and died.		Apparently healthy
239	47	F	Extraction of tooth.	Conical sponge	P	Coincidentally with extraction of tooth, P stopped Artificial R., dashing of cold water and faradism, did not restore animation.	Syncopa. P.M. Heart fatty degeneration muscular structure of tawny colour, easily broken down under pressure microscopically only one thick line of healthy muscular structure beneath visceral pericardium, the rest in advanced fatty state	Sitting posture.
240	37	M	Puncturing enlarged liver		P	P suddenly failed patient turned blue and gasped. Artificial I. and galvanism employed without success for 1 hour Artificial R rather embarrassed as patient on bed in corner of ward.	Syncopa P.M. Liver greatly enlarged, lardaceous containing numerous gummatous masses, closely adherent to diaphragm	
241	29	M	Amputation of thumb (5 minutes).	$\frac{1}{2}$ oz.		5 minutes after commencement of administration was convulsed skin of chest neck and face became purple and breathing stertorous. Breathing ceased. Artificial R and galvanism resorted to. Efforts abandoned after 20 minutes.	Chloroform and alcoholism Died from coma an infrequent form of death from anæsthetics P.M. Lungs slightly congested. Mucous membrane of wind pipe slightly red dened. Heart empty left ventricle contracted. Right flaccid valves normal. Kidneys congested. More cerebro spinal fluid than usual	
242	46	M	Reduction of dislocated shoulder joint.			Luxation reduced but patient was dead. Usual efforts made for resuscitation	? Syncopa.	
243		M	Reduction of old-standing dislocation of shoulder joint			When bad symptoms came on venous injection of ammonia used with no result		Had been hard drinker
244	30		Passing catheter for stricture of urethra.	Sponge tent 2 dr		Stage of excitement violent, arms and legs being moved violently Held breath Face became dusky Sponge removed and no more chloroform given Struggling continued and still held breath Face became more livid Slapped with wet towel which did not cause him to inspire. Face became darker and struggling ceased. Artificial R caused some return of P after $\frac{1}{2}$ hour also galvanism, but no permanent good.	Over distension of right side of heart caused by violent movements of extremities and forcible holding of breath P.M. Right side of heart gorged with fluid. Lungs deeply congested. Bladder thickened and dilated.	
245		M	For epithelial cancer of lip					
246		F	Removal of cancer of breast.					
247	0	M	For aspiration of abscess in submental region.	2 dr	P	Struggled much during administration of anæsthetic but became quiet. Just as more CHCl_3 about to be given for operation patient became pale and P stopped. Every means used to restore without avail.	Syncopa. P.M. Left cavities of heart empty right contained much dark brownish red fluid blood mixed with granular clot. Lungs emphysematous	Patient a heavy drinker

DEATHS UNDER CHLOROFORM
CASES BETWEEN 1860 AND 1891 FROM PUBLISHED RECORDS (*continued*)

1 Reference	2 Age	3 Sex	4 Operation and duration of administration.	5 Method of administration	6 P or R.	7 Symptoms occurring under anæsthetic.	8 Assigned cause of death.	9 Remarks.
248	50	F	For iridectomy for glaucoma in left eye.	Inhaler 1 dr 40 minims	P & R	Became rigid breathing stertorous, hurried and uneasy. R. watched and patient tried to eject saliva. Drove deep inspiration and ceased to breathe. P stopped. Measures taken were: Wet towel, ammonia to nostrils, artificial R. (Silvester's method) only 1 or 2 efforts of breathing followed.	? Syncope. P.M. Anterior surface of heart loaded with fat, posterior wall of right ventricle very thin, muscle being apparently encroached on by fat, but no fatty degeneration. Aorta dilated and rigid with atheroma in atherosclerotic deposit, right auricle distended with fluid blood, valves healthy.	Patient had had same operation performed for right eye and chloroform was given from same bottle on each occasion. The chloroform was supposed each time to be methylene bichloride, but subsequent analysis showed that it was chloroform.
249							P.M. Right ventricle of heart dilated and fibres undergoing fatty degeneration.	
250	48	M	For fistula in ano.	Int. 1 dr	P	P ceased. Measures resorted to were: Drawing out tongue, artificial R. slap-plug, chest over heart with wet towel, ammonia to nostrils. Breathing feebly continued, after which two distinct gasps and patient died.	? Syncope.	Patient had taken CHCl_3 before with out difficulty.
251	23	M	Operation on finger.	(1) Bag apparatus (Clover's) (2) blowing apparatus (Junker's) (3) bag apparatus (4) blowing apparatus	P	Inhalation begun with bag apparatus and continued with blowing apparatus but owing to vomiting former was substituted. When patient was under an exploration of growth before operation, caused delay, and he became half-conscious. Blowing apparatus again used, patient drew in too much air through tube so cambric handkerchief was placed over face. Then P became weak and pupils dilated. Was laid on floor, artificial R. (Bain's and Silvester's methods) tried to assist natural R. which still continued after I ceased. Ammonia near mouth, cold affusions, hot cloths over chest also tried and artificial R. continued for 1 hour. No return of P.	P.M. "Inhalation of chloroform. Syncope when the handkerchief was laid over face CHCl_3 vapour too strong for an enfeebled heart. No I.M., so the heart could not be examined but the above reckoned the most probable cause of death.	
252		M	Removal of adenoid growth at back of nares.		P & R	Suddenly I and R ceased. Artificial R. kept up nearly $\frac{1}{2}$ hour with no response to it at any time.	? Syncope.	
253		M	Removal of scrofulous tumour of jaw.		P & R	Patient soon began to struggle and CHCl_3 discontinued. Alarming symptoms came on and artificial R., electricity &c., employed for nearly 1 hour with no avail.	? Syncope. P.M. appearances <i>nfi</i> . Heart showed no disease.	Patient slightly under drink when about to be operated on. By auscultation heart found to be weak, and CHCl_3 given very carefully.
254	47	M	Reduction of dislocation of humerus.	Small quantity	? P			Patient strong healthy looking. A drunkard and past slouter.
255	48	M	Amputation of second finger.	Int. 2 dr	R.	Patient gave 2 or 3 snorts, became livid. R. stopped and I very faint at wrists. Artificial R. (Silvester's method) with cold affusions, galvanism to heart and diaphragm and ammonia to nostrils. Heart beat faintly at end of 20 minutes, but no R.	Failure of R.	
256		F	Extraction of pin from back of hand.			Fatal symptoms set in immediately after operation, and patient died.	? Syncope. Heart very flabby. Fatty degeneration.	
257		M	Dental.				Syncope.	
258	14	M	Examination of dislocated hip (2 minutes).	1 dr	? P	Patient seemed half sensible then fainted, and state became dangerous. Artificial R. (Silvester's method) and galvanism tried without effect.		
259		F	Extraction of a tooth.				Syncope.	Sitting posture.
260	19	M	Amputation of third toe.	On fold of Int. $\frac{1}{2}$ dr	P	About end of operation P fainted and face became pale and livid. Window opened, water thrown on chest, pillows removed. R. became stertorous then faint. Liquor ammonia to nostrils, friction and brandy to extremities. Artificial R. and inversion (Nelson's method) and galvanism. No return of P or R.

CASES BETWEEN 1860 AND 1891 FROM PUBLISHED RECORDS (*continued*)

1 Reference.	2 Age.	3 Sex.	4 Operation and duration of administration.	5 Method of administration.	6 P or R.	7 Symptoms occurring under anæsthetic.	8 Assigned cause of death.	9 Remarks.
261	6	M	Removal of tongue for epithelioma by galvanic cautery (10 minutes)	Lint. 3 dr	R	R became irregular and ceased. No stertor, failure of P or pallor. Before R. ceased, artificial R commenced together with application of cold to chest ammonia to nose, and galvanic current to diaphragm. These, with nutritive enemata, continued for $\frac{1}{2}$ hour. Pupils dilated. Heart beat some little time after R. ended.	Paralysis of nervous centres of R. P.M. Brain and heart healthy. Blood throughout body black and fluid. Lungs healthy both pleuræ adherent to thorax and diaphragm. Trachea and bronchi contained much grumous mucus.	Patient had suffered from epithelioma for $2\frac{1}{2}$ years, and for 3 weeks preceding the operation had only been able to take liquid food.
262	48	M	Amputation of little finger	Folded towel	P P	Struggled violently face became livid. All means of resuscitation without avail	? Syncope.	Patient healthy man.
263			On canceroid of penis by galvanic cautery	Funnel compress with plug of lint 12 15 grm.	P	Became pale, P stopped. R was suspended and all efforts to restore animation useless		
264	4	F	Removal of eye.	Flannel stretched on wire inhaler Less than 3 dr	P	P suddenly stopped though breathing continued. Died while under influence of CHCl_3 . Every means used to restore patient but of no avail. Means used were Artificial R (Nelson's method), battery, and cold affusion.	? Syncope P.M. All organs healthy except heart in which was growth about size of nut in anterior wall of right ventricle and projecting into interior of cancerous nature. Suffocation caused by impeded circulation of blood. P.M. Heart healthy cavities empty, lungs diseased, cavity with pus in right lung left lung consolidated and pleuritic adhesions. Liver softened and quantity of pus in peritoneum as result of peritonitis	Heart had been examined but no evidence of disease found.
265	21	F	Puncturing abscess in abdomen.		?	When operation about to be begun, violent vomiting came on. CHCl_3 withdrawn, vomiting ceased and patient became partially conscious, then gave a gasp and died.		
266	11	M	Reduction of paraphimosis.			At close of operation patient ceased breathing. Nelson's method resorted to produced a few gasping Rs but all other efforts in vain. No assistance could be obtained till 30 minutes after patient's death.		
267		M	Removal of toe-nail.			"Got a whiff or two of CHCl_3 and was dead. He was sitting up.		
268	49	M	Reduction of dislocation of shoulder	2 dr		At moment of reduction of dislocation slight shudder and tremor passed over patient. Inversion pulling forward tongue with artery forceps, and other means, tried without success.	Paralysis of heart I.M. appearances nil	
269	51	M	Cauterisation of ulcer on left leg (5 to 6 minutes).	Linen, funnel shaped, with cotton wool at bottom 720 grm.	I & R	Lividity cessation of P and R. Measures resorted to were Opening windows cold water affusions friction over cardiac region two slight inspirations next inversion, artificial R. application of hot iron over epigastrium and soles of feet.	Sudden paralysis of heart producing syncope. P.M. Lungs healthy some pleural adhesions easily separable, especially on left side blood dark and fluid. Pericardium closely adherent to heart. Heart lax and collapsed. ? Syncope. P.M. Lungs healthy. Heart deposit of fat on surface, but healthy aorta ratheromatous. Liver surface with one small nodule (epithelioma). Kidneys granulated and contracted.	Strongly built, thin, with well developed muscles. No appearance of cachexia. Had had ulcer for 20 years, much suffering for $\frac{1}{2}$ year before death.
270	6	M	Removal of superficial sequestrum from surface of left thigh bone.	Long cone. 1 dr	P & R	Lividity R. irregular and noisy. Patient turned over to left and tongue pulled out. Breathing and P became good. Operation then commenced patient again became livid, breathing noisy and irregular. P and R. then ceased for 20 minutes attempts at restoration were made by artificial R. (Silvester's method) galvanism ammonia injection (intravenous) friction cold applied to chest walls—all with no avail.		Stout and muscular no external signs of organic disease. Slight arcus senilis. Anxious, timid and sensitive to pain.

278	53	M	Removal of finger	Less than 1½ dr		Livid though R regular sterior Measures resorted to were Drawing out tongue artificial L. (Nelson's and Silvester's method) for ½ hour with no avail	? Syncope	Patient thoroughly examined before operation as to state of heart.
279	21	F	To pass aspirating needle into tumour	About ½ oz		A good deal of struggling at commencement of inhalation, and just as needle was to be plunged into abscess vomiting came on When the vomiting had ceased partial consciousness had returned and more chloroform was about to be given when a gurgling noise was heard then patient became ghastly pale and died Artificial R was resorted to with no avail.	° Syncope I M Pleuritic adhesions over the sides and bases of both lungs, and over the middle lobe of the right lung there was a small abscess containing 2 oz of pus. Partial consolidation of each base. Heart healthy and empty. Large abscess in left iliac fossa of abdomen nearly up to umbilicus. Source of abscess not traced. No inflammatory lymph over intestines which appeared healthy. Brain normal said to be automic	Patient had pleuropneumonia about May 26 From that time till July 7 the chest symptoms improved. About June 5 tenderness over left ovary was noticed and this increased till July 7 when the operation took place
280	25	F	Obstetric for version		P & R.	As patient did not wake after inhalation house surgeon (not hitherto called) sent for I thereby face blue breathing very imperfect Restorative measures unsuccessful; died 10 minutes after house surgeon's visit.	? Syncope	
281	27	M					I M " Death from chloroform General emphysema of lungs	

Clinical Lecture

ON A

CASE OF HYDROPERITONEUM.

Delivered at the Middlesex Hospital, March 4th, 1893,

By J BLAND SUTTON, F.R.C.S. Eng.,

ASSISTANT SURGEON TO THE MIDDLESEX HOSPITAL.

GENTLEMEN,—It is customary to refer to all collections of fluid in the peritoneal cavity under the term "ascites." Free fluid in the abdomen may arise from abnormal conditions connected with the circulation, such as heart or renal disease, and from obstruction to the portal circulation, to accumulations of fluid arising from such causes the term "ascites" should be restricted. When the fluid is secondary to disseminated nodules of cancer ovarian sarcoma, peritoneal warts, adenoma of the Fallopian tubes, or to salpingitis, the collection of fluid should be referred to as "hydropertoneum." We have had recently, in the Helena Ward, a very instructive case in relation to this matter which induces me to bring the subject under your consideration. Many of you will remember that in January last Mr Arthur Wyborn sent

FIG 1

A warty ovary T Tube. P Parovarium. L, Ligament of ovary

me a female patient with a note to the effect that she was suffering from some serious ovarian or uterine disease. The patient stated that she was forty one years of age, single, and had ceased to menstruate for five years. She had for many months suffered from constipation, and that difficulty had increased during the past six weeks. The patient looked ill. On examining the abdomen it was found to be distended below the umbilicus and although I satisfied myself that there was free fluid in the peritoneal cavity I pointed out to you that the physical signs were not characteristic of ordinary ascites. On examining the pelvic organs the uterus was natural in size and position but no tumour was detected through the vagina. On rectal examination a soft mass external to the bowel could be felt pressing upon and narrowing its lumen, but not invading its wall. The patient was advised to come into the hospital. On her admission seven days later the fluid in the abdomen had considerably increased in quantity, otherwise the physical signs remained the same. The urine was normal in quantity and free from albumen. The patient was examined by a medical colleague, who pronounced her free from cardiac or pulmonary trouble, there was no oedema of the extremities. I invited some of my surgical colleagues to examine the case, but they were unable to throw any fresh light on it and it was deemed advisable to recommend the patient to submit to an ex-

ploratory operation. To this she assented without the least hesitation.

The abdomen was opened on Feb 4th, in the same manner as for ovariectomy, and a large quantity of fluid at once gushed out. On introducing my hand into the abdomen I found the left ovary replaced by a large soft, warty mass, the size of two closed fists. The tumour was carefully withdrawn through the incision, and its pedicle transfixed and tied with silk. I found the right ovary in a similar condition, but much smaller (See Fig 1.) This was removed. The abdomen was then flushed with warm water, and on examining the pelvic peritoneum it was found beset with a velvety mass of soft pink warts which bled freely when they were rubbed with the sponge. The uterus was small, but otherwise normal. The abdominal incision was closed with waxed silk sutures, the wound dressed, and the patient returned to bed. She made an uninterrupted recovery and left for a convalescent home three weeks after the operation. The tumours were typical examples of papillary cysts arising in that portion of the ovary known as the paroöphoron, the warts, as I have had several occasions of demonstrating to you, arise from the inner walls of the loculi and often grow so luxuriantly and lead to such distension that the walls rupture and

FIG 2.

A villous tumour (papilloma) of the kidney

become everted, allowing the warty masses to project freely into the peritoneal cavity. In some of the loculi the warts perforate the cyst wall and project partly into the cavity of the cyst and partly into the peritoneum.

On microscopical examination these papillomatous masses will be found to conform to the structure of warts which occur in other situations but the epithelium which surmounts them is very abundant and easily detached, this explains the abundance of cells found in the fluid which escaped from the abdomen. It frequently happens that surgeons are alarmed when they find warts on the peritoneum, they at once regard the case as one of malignant disease, but, as I have told you on other occasions, there is no ground for alarm, as the warts will quickly disappear after the primary tumours have been removed. In this respect these warts are in agreement with what we know of crops of warts on the skin. They often occur suddenly and almost as suddenly disappear, indeed, the life of warts is often very transient. So with peritoneal warts, but as long as the seed supply continues new warts spring up, last for a time and then die, to be succeeded in their turn by a new crop. Remove the tumour, the supply of germ-epithelium ceases, the warts die and the crop is not

replenished. The explanation of the predilection of the warts for the recesses of the pelvic peritoneum is due to the fact that when the body is at rest the detached cells in the peritoneal fluid sink to the lowest level and thus naturally fall into the pelvis. The quantity of cells in the fluid free in the abdomen in these cases is very great, hence, had we removed a small quantity and examined it under the microscope, it would have led us to believe that this woman was suffering from a cancerous tumour, but my investigations have taught me to place very little reliance on the microscopical characters of fluid removed from the abdomen in cases of hydro peritoneum, and for some years I have disregarded this method as an aid in diagnosis.

Let me remind you that there are other situations where papillomata may give rise to secondary tumours. For instance, we have in the museum this rare specimen (see Fig 2) of villous tumour (papilloma) of the pelvis of a kidney. The specimen was obtained by Dr Murchison from a man sixty five years of age, the opposite kidney was affected in a similar manner, but an interesting feature in the case was the existence around the vesical orifice of each ureter of a villous tumour of the same structure as those in the kidneys. It is not improbable, from what we know of the habits of warts generally, that in this instance the vesical warts were due to transplantation of epithelium from the pelvis of the kidney to the bladder. This case should teach us in conducting *post-mortem examinations on cases of villous tumours of the bladder* to carefully examine the pelvis of the kidneys. I should like to discuss with you the relation of the papillomatous masses of the ovary to the hydropertoneum let me reserve this for a future occasion, but be good enough to carry away with you this important lesson whenever you have to treat a case of hydropertoneum—that is, free fluid in the peritoneal cavity unassociated with cardiac, renal or hepatic disease—do not rashly come to the conclusion that it depends on the presence of cancer, even though the fluid may exhibit under the microscope a host of epithelial cells.

ON SOME CLINICAL VARIETIES OF CHRONIC ALBUMINURIA, CHIEFLY WITH REGARD TO PROGNOSIS¹

By C H RALFE M.A., M.D. CANTAB.
PHYSICIAN TO THE LONDON HOSPITAL ETC.

THE clinical significance of albuminuria has, undoubtedly, considerably diminished in importance during the last twenty years. Referring to text-books published about that time, one finds hardly any mention of the fact that albumen might appear in the urine independently of disease of the kidneys, or if spoken of, it was recorded as "highly exceptional" and "unimportant." Moreover, in consequence of the fatality attendant on recognised inflammatory diseases of the kidneys, the presence of albumen in the urine came to be regarded as a symptom of the gravest import. Since, however, the practice of systematically examining the urines of all patients for albumen, as well as those of a presumably healthy class, that present themselves for life assurance and for the public services, came into vogue a numerous and well defined group of cases has been determined, which for convenience may be designated as "functional," and which perhaps constitutes from one third to one half of all the cases of albuminuria that come under observation. Besides which, with regard to the albuminuria associated with actual disease of the kidneys, the earlier recognition of the symptom, owing to the systematic examination of the urine—now, it is to be hoped, universally employed—points to the mischief in the primary stage of its inception before the structure of the kidney is irreparably damaged, and permits, by improved dietetic and hygienic measures, of checking its advance, and possibly in acute forms its recurrence. This has made the prognosis of albuminuria not only more hopeful, taken as a symptom generally, but even in the graver cases, when associated with renal disease, less immediately fatal than was till quite recently the case. It is in respect to this latter class of albuminuric subjects that I wish to invite discussion and I venture to express the opinion that, when early recognised, and when the patient has been placed under

proper supervision—dietetic, hygienic and therapeutic—these forms of chronic albuminuria collectively known by the term "Bright's disease" have a less dark prognostic future before them, but are even, for a time, susceptible of a very distinct amelioration. But in these cases (organic renal disease) there are such clinical varieties depending etiologically on the constitution of the individual—heredity, specific conditions, such as gout, syphilis, struma &c., either acquired or inherited, specific poisons, such as scarlet fever, diphtheria, lead poisoning and the like—which have to be taken into consideration in coming to a conclusion as to the course any given case has to run, that nearly every case presents itself as showing some variation worthy of notice, either as affecting the predisposing or exciting causes or influences, or conditions that accelerate or retard the advance of the disease. I now propose to submit a few of the most important of these clinical variations and their influence on the prognosis of the disease.

The most familiar varieties of chronic albuminuria which present themselves are those which eventuate in the small red and small white granular kidney. Though so frequently coming under observation, still, owing to the insidious nature of their onset, they are rarely observed in their earlier stages, and there is therefore comparatively little information regarding their evolution, and the possibilities of arresting or retarding their development. When they do come under observation the disease is usually far advanced, some decidedly unfavourable symptom having drawn attention to it. Taking the cases associated with small red kidney first into consideration, and excluding hospital patients in whom the systematic examination of the urine when first coming under observation draws attention at once to the condition of the kidneys (and the same may be said of those presenting themselves for life assurance), attention is usually drawn to the true character of the disease by some symptom which denotes how far it has already advanced—as, for instance, attacks of asthma (renal dyspnoea), failure of sight (albuminuric retinitis), hæmorrhages from the mucous surfaces, and paralysis, all symptoms of most grave prognostic import, denoting advanced arterial degeneration and deterioration of the blood, after the recognition of which hopes of prolonging life are seriously curtailed, and as a consequence the prognosis of this form of renal disease is deeply gloomy. One question, therefore, I would submit is supposing the disease is detected in quite an early stage of its inception, is there any possibility of retarding its progress and rendering the prognosis somewhat brighter? As I have said, one so rarely meets with a case whose whole history is known that such a question can only be answered by the collective experience of many observers. Personally I have observed only one case, and even that not quite completely, for, happily, the patient is still living. In this instance I originally saw the patient for an attack of bronchitis in 1878, when he was fifty five years of age. A note was made at that time to the effect that there was no marked emphysema of the lungs, no enlargement of the heart, and no displacement of the apex. The pulse was 88, full and compressible. The urine was normal in general character, its specific gravity 1025 and depositing urates, there was no albumen or sugar detected. This patient again came under observation in 1882, complaining of headache, insomnia and palpitation of the heart. Physical examination showed hypertrophy of the left ventricle and displacement of the apex towards the nipple line, the pulse exhibited some degree of tension. The urine was abundant, its specific gravity 1014, and it exhibited a trace of albumen. The patient was placed on a non stimulating diet, chiefly milk, fish, farinaceous food and white meats whilst red meats, wine and coffee were forbidden. He went to Homburg that summer with the result for a time that the albumen disappeared. He has now been under observation for eleven years, with the result that, with the exception of a slight outward displacement of the apex of the heart to outside the nipple line, of a more palpable thickening of the radial vessels, of the more constant passage of albumen, and of a urine of low specific gravity, he has not altered much for the worse during that period. He has adhered steadily to the diet prescribed for him from the first, and certainly up to the present time has not developed any serious symptoms of the disease, though of course it is impossible to say how long his vessels may resist the tension in them or how far they have escaped degenerative changes, and his life may yet be prolonged. Still such a case is instructive, in that under moderate dietetic restrictions the disease

¹ A paper read before the Medical Society of London on Feb 20th, 1893

has not made further advances during the eleven years it has been recognised. When one reflects that this form of chronic renal disease is markedly hereditary it is possible, by keeping a watch for any manifestations of renal disease or antecedent cardio-vascular trouble and by placing the patient under proper dietetic control, to greatly hinder the advent of those symptoms which one is unable to combat successfully when once they have made their appearance.

With regard to the form of chronic albuminuria associated with the pale or mottled granular kidney, owing probably to the symptoms being detected earlier, the immediate prognosis is not so grave as in the preceding instance. Here the prognosis of any given case depends greatly on the nature of the predisposing and exciting conditions. Thus in the chronic nephritis of gouty patients the intensity and continuance of the inflammation are influenced by the frequency and severity of the gouty manifestations. These cases run often quite a chronic course, and when patients can avail themselves of the dietetic and hygienic regulations now advocated they have been known to live many years. Thus a patient who was seen by the late Dr. Murchison as long since as 1874, for nephritis associated with gout, is still living. He has wintered ever since in some dry warm climate and has adhered to a non-stimulating and comparatively non-nitrogenous diet, and though the albuminuria has persisted throughout, he enjoys a fair measure of health, and as yet has developed no symptoms of *uræmia* or *dropsy*. Even when these symptoms manifest themselves they are not of so grave import as their occurrence in some other forms of chronic albuminuria would lead one to expect and the patients often experience relief from them on the outbreak of a frank attack of gout. In one case, a patient aged forty years, who for three years previously had suffered from albuminuria, was seized with deep coma preceded by convulsions, whilst he also had considerable oedema and almost complete suppression of urine. The case was regarded as almost hopeless, but after many hours the coma passed off, and shortly afterwards an attack of frank gout developed. He lived five years, continuing his work nearly the whole time, and had he taken care of himself, and his occupation been a less trying one, he would probably have lived even longer. In another case, a lady, the duration of life was seven years after the first attack of *uræmia*. In the nephritis occurring in patients who have suffered from syphilis or malaria, and especially those subject to lead poisoning, the prognosis is far less favourable, probably from the fact that degeneration of the vascular system occurs earlier. Indeed it may be taken as a general statement that patients rarely survive more than from eighteen months to two years after the appearance of serious hæmorrhage, either from mucous surfaces or from the vessels of the retina. Mentioning the occurrence of hæmorrhage from degenerated vessels brings to my notice a comparatively rare form of nephritis, which is attended throughout with a hæmaturia more or less persistent. Of three cases recently under observation at the London Hospital, in two the hæmaturia was moderate but constant, in the third profuse. The first case had suffered from albuminuria for about a year, during which time the urine had been bloody, the amount of blood was never excessive, being mostly observed when deposited as a fine red line on standing. The albumen was not excessive, and after the patient had been kept at rest in bed and on a milk diet it became merely a trace. Still blood corpuscles were always to be found on microscopic examination, and on frequent occasions crystals of free uric acid. He suffered at the same time from eczema of the scalp. His general health was not impaired, and whatever the cause of the hæmorrhage it did not apparently proceed from vascular degeneration. The second case was that of a young woman aged twenty-three who was admitted to the London Hospital suffering from hæmaturia. This at first was supposed to be due to possible renal calculus, but a close observation negated that supposition, and there was no doubt that she was suffering from chronic nephritis. She was nearly three months in hospital, and during the whole time very definite traces of blood were always found in the urine, whilst the amount of albumen was never great. In this case the deposit of uric acid crystals in the urine was frequent, and her father was stated to have suffered from gout. In the third case, that of a man aged thirty-eight, who was under the care of a colleague, the hæmorrhage was profuse. The patient had suffered from acute attacks of gout since the age of eleven, and for some years past had suffered from hæmaturia, alternating with the gouty paroxysm. In this case, as in the others, there was no evidence of vascular

degeneration, nor was the patient's health impaired to the extent usually found in chronic nephritis, and the disease, whatever its nature, was apparently running a comparatively mild course. The albuminuria became merely a trace whilst the patients were kept on a milk diet and at rest, and had it not been for the continued presence of blood in the urine little importance would have been attached to their condition. In another case of hæmorrhagic nephritis somewhat similar conditions were observed, only the attacks were paroxysmal, so that had it not been for the presence of actual blood in the urine it might have been taken for hæmoglobinuria. The patient's (himself a medical man) account of his attacks were briefly as follows. On the first occasion he had been feeling distinctly unwell three or four days before, with a vague feeling of malaise, biliousness, noises in the head and intense languor. Then came a distinct rigor, the urine became scanty and smoky in colour, exhibiting under the microscope numerous blood corpuscles mixed with numerous uric acid and oxalate of lime crystals. This state of things would continue for some days and then the attack passed off, though blood corpuscles would readily reappear in the urine on any over fatigue or indiscretion of diet. The quantity of albumen observed at any time was always comparatively a mere trace, and that not always observable in each sample of urine passed in the twenty-four hours. Before I saw him he had three such attacks and I saw him just after his last. His urine contained only a trace of albumen but many blood corpuscles and crystals of uric acid and of oxalate of lime. I should state that during the paroxysms his pulse, which was usually soft, became hard and tense. A case somewhat like this, only the hæmorrhage was more profuse I have seen from time to time during the last nine years. He was originally sent as supposed to be suffering from renal calculus, as he complained frequently of paroxysms resembling renal colic and profuse hæmaturia. That his trouble was not caused by stone was soon proved, since it was evident the paroxysm did not follow exertion, and also as soon as the hæmaturia cleared up, albuminuria persisted in considerable amount, whilst the urine contained casts of recent and old origin. In this patient the paroxysms were preceded by the same feelings of malaise as in the other patient. Both cases improved greatly when placed on a non-stimulating diet and both had a prolonged rest, the first passing a winter in Egypt, the other living for some time in a mild and sheltered spot in Ireland. The first patient reports that since his return he has rarely experienced a paroxysm, and that only at long intervals and in very slight degree. The other states that he has had no paroxysmal attack since he has developed gout freely in his knees, wrists and smaller joints. It is interesting, in considering the nature of this hæmorrhagic nephritis to bear in mind that the nephritis occurring in malarious subjects is especially distinguished by its hæmorrhagic character, caused, no doubt, by the intense congestion of the abdominal viscera. May one therefore not conjecture that the gouty poison may have a similar effect in cases where the hæmaturia is distinctly of a paroxysmal character, and that the kidney itself is the seat of a true gouty inflammation.

So far I have been considering chronic albuminuria as the result of a hyperæmia more or less active, and must now consider the albuminuria resulting from passive congestion. Of late years this has not received the attention it deserves, partly because attention has been more fixed on those chronic forms of nephritis associated with cardio-vascular changes and increased arterial tension, and partly because such cases are less numerous in hospital practice than amongst private patients. In its most complete form this albuminuria is met with as a result of valvular disease of the heart, causing what is termed 'cyanotic induration of the kidney.' So far as prognosis is concerned in cardiac disease, the appearance of albumen in the urine denotes nothing more than the increasing failure of the right side of the heart and stasis in the renal veins. But there are also other cases in which venous stasis undoubtedly plays a part in causing a chronic albuminuria independently of actual disease of the heart. These occur chiefly in middle-aged persons who either from hereditary predisposition or too free indulgence in rich food and generous wines, have become obese, especially as regards the deposition of fat round the abdominal viscera. Such individuals are of a lax constitution and usually have a feeble circulation, as a consequence of which assimilation is very imperfectly performed and they require to be well supported in order that

enough material may be assimilated by their imperfect organs to carry on the vital processes. These patients, owing to the laxity and feebleness of the muscular system, take little exercise, with the result that they become flabby and, especially the abdominal muscles, relaxed, so that the abdominal viscera are not supported and the whole abdomen tends to fall forwards. This condition, together with the little exercise taken, and the amount of food ingested, adds to the already existing abdominal plethora, and after a time these patients, who have originally sought advice for relief from some dyspeptic trouble, begin to pass albumen with their urine. At no time is this ever excessive, and can be easily kept in control by diet and hygienic measures and especially by the use of mild aperient waters. In none of the cases I have had under my observation have I noticed the development of active gout or hypertrophy of the heart or degeneration of vessels, nor are uræmic symptoms usually present. When these patients die—and they often attain old age—it is from an intercurrent attack of some acute disease. So long, however, as these patients are not exposed to any vicissitude, are well fed—for in this form of albuminuria a more liberal dietary is required—and are warmly clad, they live for many years without any apparent advance of their renal trouble. This form of chronic albuminuria is often associated with an equally mild form of diabetes, both running a course together for many years. In five cases in which I have watched the progress of this double disorder, in none did it seem to affect greatly the general health. All except one who is still living, and he is sixty five years of age, lived till close on their seventieth year, whilst the average duration of the disease in these four cases was just over twelve years. It is not improbable that the albuminuria met with in morphia *habitués* is of this congestive character, at all events, I feel disposed to accept the views of Professor Huchard of Paris on this point, although the arguments on the other side as expressed by Dr Haig are deserving of consideration.

The albuminuria associated with lardaceous degeneration of the kidneys usually runs a protracted course, so much so, that one often loses sight of the case before its termination. In four cases, however, which have come under observation whilst preparing materials for this paper—one, a medical man, had suffered from enlarged liver and spleen with albuminous urine for twelve years, the second, a medical officer in the army, had been invalided from the service fourteen years previously on account of the disease, another case was that of a woman in whom the disease seemed to have followed repeated and severe attacks of ague, contracted twenty years before when residing abroad, in a fourth case, also a woman, the albuminoid degeneration was complicated with visceral syphilis, but her illness dated back many years. In fact, the chronic albuminuria of lardaceous degeneration runs, as a rule, a protracted course unless it becomes complicated with nephritis, when the downward course is extremely rapid. This unfortunately was brought under my notice last year in the case of a member of our profession. He had suffered from albuminoid disease for twelve years till, when away for a holiday, he received a chill, and suffered subsequently from hæmaturia. From this time the character of his urine changed—it became less profuse and contained casts which had not been detected before. Up to this time he was engaged in the active duties of his profession, and felt little the worse for his chronic complaint, now he became frequently indisposed, the heart, which up to that period presented nothing abnormal, now enlarged rapidly and extensive arterial degeneration soon became evident. He usually experienced an attack of gout in the spring of each year, but none developed this year, and he died in the summer from an attack of cerebral hæmorrhage.

Lastly, with regard to the forms of albuminuria not associated with renal disease, they have but slight prognostic significance, and are mostly transient and intermittent. This is so, no doubt, during the earlier years of life, up to thirty or perhaps forty, but the occurrence, especially for the first time in middle adult life of an intermittent albuminuria is often a danger signal indicating more serious mischief to follow. There may be no evidence of changes taking place in the kidneys, no enlargement of the heart, the albumen disappearing, especially after a course of Homberg or Carlsbad waters, but reappearing on the slightest provocation, till eventually undoubted evidence of contracted kidney is present. A physician consulted me in 1880 for an intermittent form of albuminuria that seemed to follow

upon slight dyspeptic troubles, and which passed away when he paid attention to the bowels. His heart and vascular system were perfectly normal. During his sojourn in Europe he had consulted many physicians, who all encouraged him by speaking of it as "a functional albuminuria." He was then a hale, hearty man of about fifty, but within four years of that time the heart became enlarged, the albuminuria persistent and his vessels degenerated. Had, I think, more attention been paid to this premonitory albuminuria and a rigid non stimulating diet insisted on, the onset of more serious symptoms might have been delayed.

Having thus briefly and very inadequately mentioned some of the chief varieties of chronic albuminuria, I hope I have indicated that the two chief factors which have an effect in brightening prognosis and adding to the duration of life in these affections are, firstly, the earlier stage at which the disease is detected owing to systematic examination of the urine of all patients who seek advice, and, secondly, the improved system of diet now insisted on. The profession is much indebted to Sir George Johnson's teaching and his advocacy of a non stimulating diet in inflammatory affections of the kidney. This of late years has taken the form of the "milk cure," feeding the patient absolutely on milk, or if not entirely possible, with the addition only of the slightest modicum of other food and that of a non stimulating character. This so-called "milk diet" is now so generally adopted that it might be considered superfluous for me to draw attention to it in this paper. But, in spite of its general adoption, there have always been some doubts expressed as to whether its administration is equally useful in all cases, and even if it may not be deleterious in some. With a view to obtaining information on this point I have instituted for some time past a series of observations on the effect of milk diet on the different forms of renal albuminuria. These observations consisted in making an analysis of the patients' urine on admission into the hospital, and after wards gradually putting them on a milk diet (from three to four pints a day). This was continued for four weeks, a weekly analysis of the urine being made with regard to the amount of urine passed and the amount of urea, albumen and total solids. At the end of these four weeks a mixed diet was gradually resumed and another analysis made. As a result, in five cases of acute or subacute nephritis with dropsy an increase of urinary water, of urea, and a diminution of albumen were observed, which, when the ordinary diet was resumed, showed a tendency to relapse. In two cases of albuminuria associated with cardiac complication a slighter improvement was manifested. With one well marked case of albuminoid degeneration the milk diet was distinctly unfavourable, so that after a fortnight's trial it had to be discontinued and a more generous dietary adopted, with distinct benefit to the patient. In three well marked instances of contracted kidney with marked vascular degeneration the milk diet was not at all well borne by the patients. In one case, on the second day of its trial the patient was seized with severe uræmic convulsions, and in the other two aggravation of already existing uræmic troubles became more pronounced on a persistence of an enforced milk diet, whilst in all three an improved condition was noticed when a more solid dietary was resumed.

From these observations amongst hospital patients and from the experience obtained from private patients I have come to the conclusion that the best results are obtained from the milk diet in cases of acute or subacute nephritis in which the diuretic action of the lactose in the milk increases the flow of urine and relieves the dropsy, whilst in cases where degenerative changes have taken place, with an already failing heart, it is better to give a more solid and more stimulating food than milk, care being taken at the same time that it is easily assimilable and not highly nitrogenous. To my own mind the employment of an exclusive milk diet in chronic nephritis is positively injurious after degenerative changes have manifested themselves, yet in the earlier or more acute stages of the disease it must form the basis of treatment, and if it cannot be persisted in should be employed either in a modified form or resorted to whenever an exacerbation occurs.

Queen Anne street, W.

ON Saturday last a purse of gold was presented to Dr Mackay by his friends on his leaving Hornby for Knaresborough, as a public testimonial of their appreciation of his services during the past five years.

SOME SURGICAL AFFECTIONS OF THE HAND¹

BY WILLIAM HENRY BATTLE F.R.C.S. ENG.,
ASSISTANT SURGEON TO ST THOMAS'S HOSPITAL SENIOR ASSISTANT
SURGEON TO THE ROYAL FREE HOSPITAL.

THE cases on which the following remarks are founded form a group of considerable interest, some of them having received very little or no attention at the hands of surgical writers, though possessing, also, much importance. In order to prevent unnecessary repetition it may be stated that when operation was performed for any of the conditions described carbolic lotion (1 in 40) was used for the instruments and for cleansing the part before incision was made, and perchloride of mercury solutions and sal alembroth gauze dressings, with wool, for the wounds. In no case did any abnormal rise of temperature follow on operation, nor was there any complaint of pain. Esmarch's bandage was invariably employed to render the part bloodless during the course of the operation.

Dupuytren's contraction of palmar fascia.—A pianoforte player aged fifty eight was admitted under my care on Oct. 29th of last year into the Royal Free Hospital for deformity of the hands. There was no history of gout or rheumatism, or of a similar condition in any other member of the family. With the exception of an attack of bronchitis ten years ago he had always been healthy. He used to tune pianofortes, and at one time, up to about fifteen years ago, was accustomed to use a tuning key, which he had to press into the palm of the right hand, there was no history of pressure on the palm of the left hand. Fifteen months before admission the patient noticed that the little finger of the left hand was slightly flexed, whilst there were also slight rigidity of the ring finger and several thickenings in the palm. This condition had gradually become worse. The middle finger of the same hand and the little finger of the right hand had only been affected during the last two or three months.

On admission, three fingers of the left hand were affected. The metacarpo-phalangeal joint of the little finger was freely movable but the first phalangeal joint was flexed to little more than a right angle and had only very limited movement. There was a hard thickening of the fascia opposite the first internode and another opposite the first phalangeal joint. A thick band extended from the centre of the palm to the ring finger, which was slightly flexed at the metacarpo phalangeal joint, this could be extended when the first inter phalangeal joint was flexed. There were two hard nodules opposite the first internode. The middle finger was only slightly affected, a thin band extending from the palm to the ulnar side of the base of the second phalanx. The right hand was not nearly so much affected. There was a hard lump on the ulnar side of the palm and a tight band stretching to the little finger, the metacarpo-phalangeal joint of which was slightly flexed. Opposite that joint was another thickened lump. A narrow band extended from the palm to the middle finger, the movement of which was not affected, and in the palm there was a thickening in the part of the fascia corresponding to that finger. Fig 1 shows well the puckering, thinning and adhesions of the skin to affected fascia, also the large nodular thickenings of the affected fascia of the left hand, it is taken from a cast of the hand. Ten days after admission he was placed under the influence of ether and after careful preparation of the hands operation was performed after the method known as multiple subcutaneous puncture (Adams). The left hand was first treated, three punctures were required in the palm at different spots to free the ring finger and one opposite the first internode of the little finger, which it once allowed of its complete extension. Another was made through the thick band which passed along the ulnar side of the middle finger. In the right hand two punctures were made, one a little above the metacarpo phalangeal joint of the little finger another opposite the same joint of the middle finger. The fingers of both hands were now freely movable, and could be completely extended. Splints were applied on the dorsal aspect of both hands. He had some pain described as itching in the hands, on the night following the opera-

tion, but no sickness from the anæsthetic. A note was made on Nov 7th "The dressings were taken off to-day and the punctures were found to be healed. The patient can extend all the fingers fully and plays the piano easily." I may say here that he then informed me for the first time that he had not been able to stretch an octave for more than eight years, and evidently enjoyed the increased freedom given to his movements. He was told to wear a splint at night for some months to come. The fibrous nodules which were so marked in this case had considerably diminished in size when he left the hospital on Nov 16th, and their complete absorption is apparently only a question of time.

There are many points of interest in this case to which I should like to draw attention. The patient was an exceptionally healthy man for his years, without family history of gout or rheumatism or anything in the nature of disease which might be considered predisposing to the affection from which he suffered. As he had been a pianoforte tuner for a long time, the question suggested itself as to whether his occupation might not have produced the necessary change in the hands, frequent use of the tuning key being in his case the exciting cause of the contraction of the fascia. It was found, however, that the disease commenced in the left hand and was most marked there, whilst the right was the hand which he always employed in tuning. My colleague, Mr Anderson, in his Hunterian Lectures, remarked that his investigations negatived the view that mere friction and pressure of the palm by tools or other objects habitually held within the hands can account for the disease. With regard to constitutional condition as influencing the occurrence of the deformity various investigators have given different opinions, some saying that gout is the cause (Dr Keen gives forty two out of forty eight cases as gouty;

FIG 1

Mr Adams calls it gouty thickening of fascia) others say it is of neuropathic origin, whilst rheumatism, rheumatoid arthritis and alcoholism have been cited with authority as the diseases on which its formation is dependent. The case of this patient would lend support to the opinion that, although a history of these various conditions may be present, the deformity is not dependent upon them, yet one would not attempt to deny that, granted the introduction of some cause for inflammation of the part, such constitutional states would render the process thus started of a more persistent and intractable character. I will again quote the excellent lectures of Mr Anderson. He writes "The situation of the initial lesions and the peculiar tendency of the new growth to feed, like a parasite upon the tissues in which it spreads and which it replaces have led me to believe strongly that the active agent of destruction is a specific micro organism, which gains access to the subcutaneous tissues through accidental lesions of the epidermis, mostly effected by the finger nails. This would explain far better than any existing hypothesis the persistent causes of the disease and its proneness to recur after the most skilfully devised operation. The almost constant limitation of the disease to the declining years of life corresponds mainly to lessened resistance in the bodily organism, and partly perhaps to senile absorption of the palmar fat cushion. The almost complete immunity of the foot is accounted for by the protection afforded by the shoes and stockings and the impossibility of contact of the toe-nails with the sole. Individual and inherited susceptibilities are exemplified here as in other complaints of known bacterial origin. Lastly, the absence of the affection in certain countries may be due either to the absence of the specific organisms or to antagonistic influences

¹ Abstract of a paper read before the South London Branch of the Metropolitan Counties Branch of the British Medical Association.

developed in the constitution by racial, climatic, dietetic and other conditions." The examinations of the affected fascia have not, so far as I am aware, yielded any definite result, but they have not proved that this view is *not* the correct one. They are being continued, and it is very likely may ultimately enable us to say that the specific form of Dupuytren's contraction is due to the entrance and slow development of a definite form of bacillus. The disturbance or inconvenience caused to the patient by the operation was so very slight and the result in increased movement of hands and fingers so immediate and great, that there need be no surprise at the gratitude of the man for what is to him an almost marvellous result. I do not consider that the operation has cured the patient, it has for a time, but he has been fully impressed with the necessity of continuing treatment by means of splints for many months. Taking the view that I do of the possible origin of the deformity and his good previous and family history, I have not told him to alter his ordinary routine of life or take any medicine to combat gout or rheumatism. I would draw attention to the condition of the fascial nodules so marked in the casts.

Trophic changes due to the pressure of a cicatrix in the palm—Wounds of the palm of the hand involving injury of important nerves are not infrequent. The case to which I now draw attention simulated wound of the median nerve in the palm very closely, and the hand exhibited trophic changes commonly seen after the normal innervation of a part has been seriously interfered with. A watchmaker aged forty-eight came under my care on Jan. 20th, 1890, complaining of numbness and tingling in the fingers and thumb of the right hand. Four months before he had broken a thin glass vase by striking it against a clock with the palm of the right hand. There was considerable hæmorrhage, and one piece of glass was removed from the palm of the hand at the time. The wound healed readily. There was then no impairment of sensation or motion. A month later he was pushing some furniture when the scar gave way and bled, a small piece of glass protruded and was extracted by the man himself. A month after that he found the hand getting stiff, and he began to have numbness and pins and needles in it, and this had been steadily increasing since, so that the man had not been able to follow his occupation. Examination of the right hand showed some swelling of the fingers evenly distributed, the skin looked more shiny than on the other hand and the furrows were a good deal smoothed out. Over the distal phalanx of the first finger there was a good deal of swelling, and on the anterior surface were three sores, the two lower being covered with dried secretion, from the upper one serous fluid exuded on pressure over the top of the finger, where there was a largish blister. The skin of this upper part of the first finger was discoloured and bluish. The thenar eminence was wasted. The patient complained of numbness and occasional pins and needles in all the fingers and in the palm for about an inch, the more proximal part being normal and the transition from the normal to the abnormal area being gradual. Only the front and tip of the last joint of the first finger were absolutely insensitive. There was a small scar between the thenar and hypothenar eminences an inch below the wrist, immediately below this scar there was a slight prominence, and when this was pressed, especially if pressure was directed upwards, the patient complained of tingling in the fingers and pricking at the point of pressure. Four days after admission an incision about two inches and a half long was made over this scar in the line of the median nerve, commencing about half an inch above the wrist and continued into the palm. A good deal of very dense cicatricial tissue was met with at the lower border of the annular ligament, but no glass or other foreign body was found. The annular ligament was divided, and the median nerve, especially the palmar enlargement and the branches from it, carefully examined. It appeared quite normal, it was considered, however, that the palmar enlargement was more flattened than it should have been, and as the most dense part of the cicatrix corresponded in position with it a piece of the scar tissue was removed from each side of the incision. About six fine silk ligatures were required for small vessels. The annular ligament was united by four deep silkworm gut sutures and the superficial part of the wound by interrupted silk sutures, in the usual manner. No drainage tube was used. The wrist was semiflexed and placed in an anterior splint.

Eight days after the operation a slough was found at the end of the index finger. The wound healed by first intention, and when the man left hospital on Feb. 8th the sores on the index finger were nearly healed. He presented himself once

at a later date, the skin was then recovering sensation in the parts previously numb, the sores had quite healed and the colour of the first finger was becoming the same as that of the others. There can be little doubt that the trophic changes in the hand were due to compression of the median nerve by the cicatrix which followed the wound of the palm. The gradual onset and steady increase in severity of the changes until, and for a time after, the operation point to this conclusion, which is further confirmed by the result of the operation.

Myeloma of tendon sheath—This case is one of tumour of a tendon sheath. Apparently simple in character, it presented a structure after removal and examination under the microscope which proved it to be of unusual composition. The patient was a female servant aged seventeen, who was admitted into the Royal Free Hospital under my care on Nov. 12th, 1892, complaining of a swelling of the first finger of the right hand. There was nothing of importance in the family or previous history of this patient, she had noticed a swelling in the situation of the tumour for the past five years and it had gradually increased to its present size. It had not caused her any pain, but was inconvenient as it interfered with the use of the hand. On the flexor surface of the first phalanx of the index finger of the right hand was a tumour about the size of a chestnut, not very hard, but firm in consistence and containing two hard nodules. Somewhat oval in outline, it extended from the first interphalangeal joint to the palm, and bulged equally to the sides. The tendon was quite free and the finger movable. The tumour could be moved from side to side, but not in the long axis of the finger. It did not appear to grow from the bone and was not at all sensitive. It was considered to be a soft fibroma having its origin in the tendon sheath. On the 14th it was removed through a longitudinal incision along its flexor surface. The superficial part was easily separated, being encapsuled, but it was more difficult to get the growth away below. It had, as was rightly supposed, its origin in the tendon sheath, some of which had disappeared in the tumour, whilst in another part dense bands from the sheath passed into it and assisted in holding it down. A prolongation of the tumour extended round the tendon and completely encircled it. The tumour was also adherent to the fibrous tissue of the sheath on each side of the tendon, and these attachments had to be cut away, there being nothing to mark the point at which the tumour ceased. After its removal about half the tendon lying over the first phalanx was exposed in the wound. Only one or two small vessels required to be ligatured, and the wound, which was closed with silk sutures, healed by first intention. The finger for a fortnight was swollen at the seat of operation on account of some effusion of blood into the wound, but movement has been permitted, which does not cause pain, and she can fully flex and use her finger, the only sign of anything abnormal about it being the presence of some thickening and a linear scar. The tumour is a lobulated soft growth in the greater part, but presenting two or three areas of yellowish change, and of harder consistence, resembling cicatricial tissue. The prolongation which encircled the tendon is of softer growth and more vascular and can still be seen to form a tunnel with the main growth, through which the tendon passed. Examination under the microscope shows the tumour to consist mainly of fibrous tissue, but scattered through the section are a number of well marked myeloid cells. Tumours containing myeloid cells such as that described here are very rare, if one may trust the published reports of microscopical examinations, and it is very interesting to find that such cells may be found in growths which have no connexion with bone or periosteum. Fibrous tumours of the tendon sheaths, from which these cannot be distinguished clinically, have frequently been brought before the Pathological and other societies, but I can only find an account of one myeloma in English literature. In a paper by Mr. Makins on Some Intra-bursal Growths, read before the Pathological Society in November, 1886, he refers to a specimen which he removed from the tendon of the middle finger of a girl of twenty. It was of three years' growth, not painful when pressed upon, and on removal looked like a typical hard fibroma. It reached to the posterior aspect of the sheath and was removed without baring the tendon. On section he found scattered myeloid cells. More recently M. Heurtaux, in an account of these myelomata, has given five cases, three of which had been under his care. They presented characters similar to those met with in the patient

under notice, were lobulated, mostly soft, grew from the sheaths of the flexor tendons in young people, were all situated on the right hand, increased but slowly in size, and do not appear to have recurred after removal. They are evidently innocent growths, to be distinguished from the sarcomata.

Backward dislocation of the finger on the metacarpus—Having recently had under treatment a case of complicated dislocation of the forefinger, I would draw attention to it, for although such cases are apparently rare I am not sure that they do not occur more frequently than is supposed and that the patient has to be satisfied with a crippled hand in consequence of a want of appreciation on the part of the medical attendant of the reason why these dislocations are sometimes not reducible by ordinary means. This is not surprising, for the text-books are quite silent on the subject. There will be found a long description of the dislocations of the thumb and the way in which it is recommended that they should be reduced, also an account of the supposed pathology of the injury, but most commonly the real cause of the difficulty in reduction in such cases, the part played by the glenoid ligament, is not touched upon. The case was that of a girl aged eleven, who came to the out-patient department of St Thomas's Hospital on Feb 1st of this year with an unreduced dislocation of the left forefinger, the result of a fall five weeks before. She had been placed under chloroform soon afterwards, an attempt had been made to reduce it, and it was supposed at the time that the attempt had been successful. The hand was placed on a splint, but on the removal of the splint swelling of the joint was still present, with pain on

the results of further investigation and experiment, all confirming the opinion that the glenoid ligament of the joint is the cause of the difficulty in reduction. This glenoid (see Fig 2) or anterior ligament, a very dense structure, occupies the interval between the lateral ligaments on the palmar aspect of each joint, it is a thick and dense fibro-cartilaginous structure, which is firmly united to the phalanx but loosely adherent to the metacarpal bone. It is continuous at each side with the lateral ligaments, so that the three form an undivided structure which covers the joint except on the dorsal aspect. Its palmar surface is grooved for the flexor tendon, whose sheath is connected to it on each side. The other surface, looking to the interior of the joint is lined by synovial membrane and supports the head of the metacarpal bone. The weakest part of the ligament is the point of attachment to the metacarpal bone, and it is here that it ruptures when the finger is dislocated. These backward dislocations have been divided into three kinds (1) simple incomplete dislocation, the phalanx not having completely left the head of the metacarpal, (2) simple complete dislocation, in which the phalanx has become displaced on the dorsum of the metacarpal bone and rests with its anterior edge on the neck of the metacarpal, (3) complex dislocation (see Fig 3), in which the phalanx occupies a similar position, but the glenoid ligament with its sesamoid bone has become turned and is interposed between the bones rendering the dislocation irreducible. The treatment which should be carried out in these dislocations is usually easy if the surgeon who first sees the case recognises the importance of the glenoid ligament and remembers its relationship to the phalanx. An attempt to reduce without chloroform by what

FIG 2.

Section through metacarpophalangeal joint (after Henle).

attempted movement, and when she was seen in the out-patient department there was still a typical dislocation at the metacarpophalangeal joint. The finger was shortened, the phalanx forming a projection on the dorsum of the hand, the head of the metacarpal bone was prominent and easily felt in the palm, the parts were swollen, somewhat red and very tender. She was admitted into the hospital, and on the following day I attempted—the child being under chloroform—to reduce the displacement by manipulation but could not do so. A strong sharp-pointed tenotome was then passed into the joint to the outer side of the tendon, under the phalanx to the middle of the dorsal surface of the metacarpal head, and being then withdrawn on the bone, the knife divided intervening structures to a point just above the neck of the metacarpal. On flexion of the finger a slight snap was heard, probably due to the giving way of a small band of the glenoid ligament which had not been divided, and the dislocation was reduced. The hand was then placed on a splint.

I published a paper in THE LANCET of Dec 22nd and 29th, 1888, on Backward Dislocation of the Fingers on the Metacarpus, and entered fully into the literature, pathology and treatment of these displacements. The conclusions to which I came were confirmatory of the investigations of some other surgeons. Mr J Adair Laune appears to have first pointed out the rôle played by the anterior ligament in these dislocations in 1837, but his observation does not appear to have attracted much attention. More recently MM Farabeuf, Palailon, Jalaguier and others, including Dr Otis, have published

FIG 3.

Diagram to illustrate position of misplaced glenoid ligament. Antero-posterior section. M Metacarpal bone P, Phalanx. c, Glenoid ligament. d Ruptured dorsal ligament (occasionally present).

is known as the dorsi flexion method should first be made, the phalanx is tilted up until it stands upon its articular end and both forefingers are placed so as to hold it in that position and at the same time press it against the distal extremity of the metacarpal bone. Under firm pressure with the thumbs against the base of the displaced phalanx it can generally be easily slid into position. It is a good plan to keep up extension on the finger and draw the base of it backwards on the dorsum of the metacarpal, so that the anterior edge of the phalanx may get well behind the ligament, to let it touch the metacarpal and afterwards press it forward. Should this not succeed, chloroform ought then to be given, and if manipulation again fail simultaneous section of the ligament should be effected, as in this case. In old standing dislocations the joint should be opened at the side and the adherent ligament separated with the point of a knife—a procedure which I have carried out with success. It is my opinion that the complicated cases of dislocation of the thumb are most frequently due to the separation displacement and doubling up on the neck of the metacarpal bone of this glenoid ligament and that similar treatment is usually indicated. The presence in it of two sesamoid bones in the case of the thumb should be recollected if section of the ligament be required, the incision being made strictly in the middle line.

Flexor ganglion.—There is another condition to which I should like to draw attention, and that is a somewhat rare form of ganglion of the flexor tendons of the fingers—one which is peculiar in many ways and which (although I believe fully recognised) has not received that amount of attention at the hands of writers on surgical

subjects that it appears entitled to from the amount of annoyance and even actual distress to which it occasionally gives rise. A patient will sometimes come for relief on account of a painful place in the palm of the hand, and usually of the right one, perfectly well localised and much increased by attempts at grasping anything, such as the handle of a door, in order to open it. The pain will have existed for a variable time, and usually for a shorter period the patient will have noticed a swelling at the painful spot. On examination it is perhaps not easy at first to find any swelling, but if the finger be flexed and careful examination made where most tenderness is felt a rounded body will be found, not so large as a pea, well defined, very hard, and attached by a pedicle to the deeper parts just at the point where it is known that the sheath of the flexor tendon of the index finger terminates in the palm. I say "sheath of the flexor tendon of the index finger," for it will almost invariably be found in connexion with the sheath of this tendon and not with that of either the middle or ring finger, though it may possibly be there. This swelling is so exceedingly hard that the diagnosis, which is generally made by those who have not previously had their attention drawn to these ganglions, is that of fibroma or enchondroma of the hand. Enchondromata, however, are quite immovable and develop laterally, not towards the palm, besides, they are not painful or particularly tender, and are multiple, whilst these ganglions are, so far as my experience goes, invariably solitary. Situated in the palm of the hand at a point where nearly all bodies are touched when grasped, it is no wonder that much pain is produced by even ordinary use of the hand, so much so some times as to compel the patient to use it as little as possible. If these apparently solid bodies be cut down upon, they will be found to permit of easy separation from surrounding parts, excepting where the pedicle is attached, pear shaped and cystic. The wall of the cyst is composed of fibrous tissue of a varying thickness and of considerable strength, contains fluid like that usually met with in ganglia, and communicates by means of the hollow pedicle with the interior of the tendon sheath, the lining of which is continuous with it. Why these ganglions sometimes develop it is not possible to say, the part of the sheath from which they spring is certainly much exposed to pressure, but these ganglions are rare and pressure alone is insufficient, even if violent and intermittent, otherwise they would be much more common. Perhaps there is some degenerative change in the sheath disposing to weakness and yielding under pressure, so permitting of a hernial protrusion. I have met with a similar swelling in the forefinger of a laundress, situated at the line marking the junction of the palm and the right index finger on the flexor aspect. In this case there was no chance of verifying the diagnosis, for the woman, who was in bad health, refused to have anything done, although she complained of excessive pain and the hand was almost crippled, but it was probably of the same nature. In the case of these ganglions I do not think one can do better than cut down on them, separate them from surrounding parts and cut across the pedicle where attached to the sheath. An incision about an inch long in the line of the flexor tendon directly over the swelling, with retraction of the soft parts, usually gives ample room and enables the cyst to be removed without bruising or undue disturbance of the parts. In some cases doubtless a severe blow or strong pressure over the cyst will rupture it, but the immediate result is very painful and in those of any long duration unlikely to succeed. A curious instance of at least the temporary cure of a case came under my observation some years ago. A girl aged about sixteen was coming to have a cyst of this kind removed by operation, but when about to descend from a tramcar the horses suddenly started, and she, forgetting the painful hand, made a violent clutch at the rail of the car to save herself from falling, felt severe pain in the situation of the cyst, which caused her to scream out, and found that the swelling had disappeared. No trace of it could be felt by any of us when she showed the hand soon afterwards, and she has not come under observation again. Here the cyst was only of the duration of a month or two, and the walls very likely only consisted of thin membrane.

Whilst on the subject of these rarer kinds of cyst arising from the flexor sheaths, I will give short notes of a case in which two more like those seen about the wrist developed on the flexor surfaces of the index and middle fingers. The patient was sent for my opinion as to the advisability of submitting to amputation of the end of the right forefinger on account of a lump which had been

painlessly growing in the pulp for a period of six months and which was still increasing in size. She thought that it had commenced in the skin, for it was movable at first, but lately it had become more fixed. There was a rounded, fluctuating swelling which caused a uniform enlargement beyond the line of the last interphalangeal joint, and was quite fixed, tense and fluctuating. This I considered to be a cyst, possibly connected with tendon sheath. Gas was administered and a lateral incision gave exit to glairy fluid, the cavity, lined by a glistening membrane, contained no growth and extended deeply to the periosteum. It was washed out with a carbolic solution and firmly wrapped with a strip of antiseptic gauze. Ten days later she told me that she thought there was another and a similar swelling in a corresponding position in the middle finger, this was so, and similar treatment, without anæsthetic, was carried out. Both these cysts were cured by this treatment.

Manfield-street, W

A CASE OF RUPTURE OF THE OESOPHAGUS

By BRIGADE SURGEON LIEUTENANT COLONEL C E HARRISON, M B LOND, F R C S ENG, GRENADIER GUARDS

A WAR OFFICE superintending clerk aged forty seven came under my care on Jan 3rd complaining that he had attacks of vomiting at intervals of three or four days, and eructation of fluid into his mouth. He had on previous occasions been under treatment for dyspeptic symptoms. The history was as follows.—He had been losing flesh for about six months, and his appetite had rather failed of late. On Dec. 20th, 1892, he had an attack of diarrhoea and, following this, the vomiting and eructation of fluid, for which he sought advice. The amount of fluid rejected on the occasions when he vomited was considerable and led to the opinion that there was some dilatation of the stomach, and possibly some obstruction to the passage of food from the stomach into the duodenum. The patient himself was conscious of this and described the sensation which he felt of the food gradually collecting in the stomach until it was rejected by vomiting. The loss of flesh gave ground for suspicion of malignant disease. The abdomen was not distended, and on careful examination no tumour or enlarged glands could be felt. On palpation over the stomach splashing sounds could at times be heard. He suffered no pain and had never vomited blood. A microscopic examination of the vomited matter revealed no blood or sarcinae. The tongue was generally clean, or slightly furred after an attack of vomiting. The urine was natural, and the bowels acted regularly. The heart-sounds were clear and nothing of importance could be detected in the lungs. A mixture containing bicarbonate of potash, bismuth, nuxvomica and gentian was ordered to be taken before meals. On the afternoon of Wednesday, Jan 18th, he vomited whilst at his work, and the vomiting was repeated several times during the evening and night. On the following day (19th) an examination of the abdomen revealed nothing fresh, but he was directed to remain quiet in bed. About 3 P.M., having swallowed some milk arrowroot, the vomiting recurred, and whilst in the act of retching and vomiting he was seized with sudden and intense pain in the lower part of the left side of the chest. He remarked to his wife that he felt that something had burst in his stomach at the time the sudden pain occurred. This was followed by collapse of a marked character. Warmth was applied to the abdomen and lower part of the chest and he rallied somewhat. The pulse remained rapid and weak, and hurried respiration with some difficulty in breathing appeared. The tone of his voice was altered, being of a higher pitch than was natural to him. The temperature was subnormal. Towards midnight subcutaneous emphysema of the neck, cheeks and upper part of the chest developed. On examining the chest the area of cardiac dulness was observed to have disappeared and this region and the upper part of the left lung were found to be hyper resonant on percussion. Respiratory sounds were feeble, though present over the left lung in front and exaggerated over the right lung. The possibility of a chronic gastric ulcer having led to a perforation of the diaphragm into the mediastinum suggested itself as an explanation of

the subcutaneous emphysema of the neck and face. A small hypodermic injection of morphia over the seat of pain gave relief and afforded some sleep. The emphysema, however, gradually increased, the pulse became weaker, and the patient died at 4.30 A.M. on Jan. 20th, about thirteen hours and a half after the sudden access of pain and collapse.

Necropsy thirty-two hours after death.—There was very marked subcutaneous emphysema of the face, neck and upper part of the chest. The emphysema could be detected as low as the groins. The abdomen was distended and tympanic. On incising the left side of the chest there was a rush of air from the left pleural cavity. The left lung was seen to be partially collapsed. Each pleural cavity contained about a pint of dark grumous fluid, having the odour and appearance of the contents of the stomach. There was air in the loose areolar tissue of the mediastinum, as also here and there in the subpleural tissue. On the right side of the chest some old pleural adhesions were found, as well as a small cheesy nodule in the right lung. On the left side the lower portions of the pleural surfaces were hyperemic and in an early stage of inflammation. On lifting forward the lungs the loose areolar tissue around the lower part of the œsophagus in the posterior mediastinum was found discoloured and distended with the same dark fluid which had found its way into the pleural cavities. The œsophagus having been cut across high up in the chest and then carefully slit up with scissors a longitudinal rent an inch and a half long was found in its walls just above the diaphragm. The edges of the rent were sharply defined and gave no evidence of induration or of a pre-existing ulcerative or degenerative process. They bore no indication of post-mortem softening. No constriction or dilatation of the œsophagus existed, and no pouch or thinning of its walls could be detected. The heart was small but healthy. The stomach was rather dilated and was also distended, as were the intestines, with air. There was no evidence of post-mortem digestion of the walls of the stomach, which contained some thick dark fluid of the same character as that found in the pleural cavities. At the pyloric orifice a small nodule of carcinoma was found, and the whole circumference of the orifice was more or less thickened and indurated by the disease, which affected chiefly the posterior surface. The liver and spleen were small. There was nothing abnormal detected in the kidneys. The perforation, therefore, which had caused the sudden collapse and had given rise to the subcutaneous emphysema had occurred in the lower part of the healthy œsophagus immediately above the diaphragm, and had thus allowed, during the act of vomiting the entrance of air and fluid from the stomach into the posterior mediastinum and the pleural cavities.

Pearls.—Rupture of the healthy œsophagus is an accident of such extreme rarity that the details of such a case are worthy of record. This subject is dealt with minutely in a very interesting article in Von Ziemssen's 'Cyclopædia of the Practice of Medicine,' vol. viii. page 99. In this article he states that the number of well established cases i.e. 'those in which the symptoms during life, together with the post-mortem discoveries distinctly prove that the rupture of the œsophagus found at the necropsy took place during life and must be considered as the only cause of death,' amounts to nine. The references to these cases are given as follows: Boerhaave, *Atrocis nec descripti pntis Morbi Historia*, Lugdunum Batavorum, 1724; Dryden, *Medical Commentaries* Edinburgh, 1788, vol. iii. p. 308; Oppolzer, *Wiener Medicinische Wochenschrift* 1851, p. 65; Habershon, *Pathological and Practical Observations on Diseases of the Alimentary Canal*, London 1857 publishing the report of a case by Mr Comley (this case is also published in Guy's Hospital Reports April 1843, vol. i., p. 113); Jos Meyer *Medicinische Vereins-zeitung in Preussen*, 1853, Nos. 39, 40, 41; Granatzki, *Königsberger Inaugural Dissertation*, 1867; Griffin, *THE LANCET* Sept. 4th, 1869, p. 337; Charles *Dublin Quarterly Journal of Medical Science* 1870, vol. i. p. 311; and Fitz, *American Journal of Medical Sciences* Jan. 1877, p. 17. The last named paper by Fitz, besides the very full report of the case which forms the subject of his communication, contains also an almost complete account of all the reported cases. He criticises them most minutely and as a result of his study of them he only admits two or three as belonging properly to the list. Boerhaave appears to have reported the first case—viz. that of the great Admiral Baron Wassenaar in 1724. A full and interesting account of it will be found in Von Ziemssen's article. The rupture resulted whilst straining in the attempt to relieve the stomach

by vomiting and the symptoms and post mortem appearances were almost identical with those in my own case. The accident occurred suddenly in all the reported cases and was brought about in two of them by violent retching in order to remove a morsel of food caught in the œsophagus or pharynx, and in the other cases was preceded by nausea and vomiting or attempts at vomiting. Von Ziemssen remarks: "From a diagnostic point of view a very important symptom is the almost constant appearance of a rapidly developed emphysema of the skin, which, appearing first on the neck above the clavicles soon extended over a large area and sometimes involved the whole surface of the body." Of eight cases there is but one in which it is not alluded to. The ninth (Oppolzer's) cannot be considered in this analysis of symptoms on account of its lack of all particulars. Dyspnoea, sometimes orthopnoea and great distress, followed the sudden onset in the cases reported and the pulse became much accelerated. With a continuous increase of all the symptoms death generally occurred in less than twenty-four hours (seven to nineteen) in one case after fifty hours and in another on the eighth day. In all the cases a rent was found in the œsophagus and always in the lower part of the canal. In Boerhaave's case the œsophagus was torn completely across, but in all the others the rent was longitudinal. In none of these cases was any tissue change found at the seat of the laceration which could be considered as a remote cause of the accident and each case must therefore be looked upon as the rupture of a healthy œsophagus. Fitz, as before remarked, rejects nearly all the published cases and would explain the occurrence of the pneumothorax and subcutaneous emphysema as probably due to a rupture of the air passages during the violent straining, and the presence of the contents of the stomach in the pleural cavities as due to post mortem digestion of the œsophagus. He considers that for rupture of the œsophagus two factors are essential—viz., the impaction of a foreign body in the canal and the exercise of great muscular force in the attempt to remove it. Von Ziemssen, however, cannot adopt the views of Fitz and accepts the nine published cases as authentic. He explains the occurrence of the rupture by the theory that a weakening of the walls of the œsophagus takes place—as has been proved to occur also in the stomach in very similar conditions—by a process of œsophago-malacia. He remarks after sketching the prominent symptoms and post mortem appearances, that "although the symptoms are totally unexplained by the supposition that the rent in the œsophagus took place merely in consequence of post mortem softening it seems wrong while fully recognising the propriety of a profound scepticism in the presence of such unusual occurrences, totally to deny the existence of rupture of the œsophagus during life so long as there is any possibility of explaining it. Now it is scarcely credible that an œsophagus with tissues intact could be lacerated merely by its own contraction or by traction exercised by neighbouring parts (diaphragm, stomach) nor could we accept this explanation even for the cases (Meyer Fitz) in which a not very large morsel of food engaged in the canal brought on violent contractions. Accordingly instead of rejecting them, we feel justified in believing that all these cases of so-called spontaneous rupture of the œsophagus may be referred to an antecedent vital œsophago-malacia—arising whilst the patient is in a healthy condition—very rapidly developed by special circumstances or surroundings." He adds "We shall not go wrong in considering that atony of the muscular tissues of the œsophagus and cardia caused by the habitual use of emetics and a tendency to regurgitation forms the disposing cause of rupture."

Guards' Hospital, Rochester row S.W.

NOTES ON THE THERAPEUTICS OF EXALGINE

By EDWARD G. YOUNGER, M.D. BRUX., M.R.C.P. LOND.,
PHYSICIAN TO THE ST. PANCRA'S DISPENSARY, LATE SENIOR ASSISTANT
MEDICAL OFFICER, NIALE DEPARTMENT, HANWELL ASYLUM.

So much has been written of late in respect of the analgesic properties of exalgine (methyl acetanilide) that I have been induced to give it a trial in suitable cases with results which seem to me to warrant their being placed on record. It appears to be generally recognised that exalgine is of great service in the treatment of neuralgic pains of a functional nature, and my own experience in this respect has

mply confirmed that of other and independent observers, but as most of the earlier cases under my own observation present no essential difference in their character or course, one or two doses of the drug almost invariably procuring immediate relief, I need only refer to one or two of the more typical

CASE 1.—A young woman aged twenty three came to me suffering from supra orbital neuralgia on the left side, which she described as of extreme severity during the paroxysms. She begged me not to prescribe quinine for her, as on previous occasions, instead of affording relief, its administration had been followed by distressing headache and giddiness. I ordered a two grain dose of exalgine to be taken immediately, the dose to be repeated every four hours while the pain lasted. The patient called the next day to inform me that the pain had disappeared within an hour of the first dose and had not since returned. She promised to return should it recur, and as I heard no more of her I am justified in assuming that the relief was permanent.

CASE 2.—A very nervous, excitable patient, aged sixty, a chronic dyspeptic, and a sufferer for many years from prolapsus uteri. She had been under my care off and on for the previous nine months, and on the last occasion she came to me complaining of unbearable pain at the top of the head, worse at night and interfering with sleep. There was some tenderness of the painful area, and she attributed her condition to an excess of family worries. I ordered one grain of exalgine three or four times a day, and on the occasion of her next visit she expressed her gratitude for the relief that had followed the first three doses both in respect of the pain and of the insomnia. When, however, she left off taking the medicine the symptoms returned, but on resuming the treatment she again experienced almost immediate relief. She asked my sanction to her keeping some of the medicine by her in case of any further trouble of the kind.

CASE 3.—This patient was aged twenty five. In the fifth month of her second pregnancy she came to me complaining of intense supra orbital neuralgia, to which she had been subject for the last three months. A single dose of exalgine at once stopped the pain, which, however, returned in a few hours, when a repetition of the dose again afforded immediate relief. She has since remained free from pain.

CASE 4.—A nervous emotional girl aged nineteen of the neurotic type. Menstruation was irregular and scanty and she complained of rather profuse leucorrhœa. She came to me on account of violent pain at the vertex with a sensation "as if something were creeping about inside the skull." I gave her one grain doses of exalgine to be taken three times daily and within two days the feeling and the pain disappeared entirely. She was then put on Bland's pill, but the headache at once returned, yielding, however, to a few more doses of exalgine. Since then this patient has had one or two recurrences of the symptoms, which, however, have invariably yielded to a few doses of the drug.

The encouraging results in these and other similar cases of pain of a neuralgic character, associated or not with other subjective symptoms or sensations, induced me to try exalgine in a number of cases of mental disease associated with similar subjective phenomena, some in an incipient and others in an advanced stage. Though perhaps the treatment may be considered empirical I think the effects justified its employment. I append notes of the more interesting of these cases.

CASE 5.—A young woman aged twenty eight first came under my care in May 1892. She then complained of mental depression and I gathered that she often wandered about London all day having no settled purpose and she was obviously unable to confine her attention to any given subject. She experienced constant pain across the forehead and in the eyeballs and a bright light caused acute discomfort. Her aspect was melancholy and suspicious, but she did not seem subject to any actual hallucinations or delusions. She was treated for a time *secundum artem* with the bromides, the ammonio-citrate of iron iodide of potassium &c., and all proved equally inefficacious. On Aug. 15th I prescribed for her one grain doses of exalgine to be taken three times daily. On Aug. 29th she returned, saying that she had been much better ever since she began taking the last medicine. The intolerance of light had altogether disappeared and the headache returned only at rarer intervals and was always relieved by a dose or two of the medicine. The mental symptoms remained unchanged. I have lately been informed by a relative, however, that since she ceased to be troubled by the pain in the head her general condition has undergone marked improvement—in fact she was "better in every way."

CASE 6.—The patient, aged forty two, was very melancholy, heard voices and saw imaginary figures. She was deaf and her aspect was peculiarly dull and heavy. She complained of a dull pain at the top of the head and sleeplessness. Since November, 1891 when she first came under my notice, she had been under much the same treatment as the preceding patient (Case 5), and with equally unsatisfactory results. In August last I prescribed for her, to begin with, one grain doses of exalgine four times a day, and within a day or two she declared the headache to be much better and sleep less disturbed. She then appeared more cheerful and hopeful, but her hallucinations remained unchanged. In this as in the preceding case, the mental condition improved to some extent coincidently with the relief afforded by the treatment in respect of the painful sensations.

CASE 7.—In this case the patient, aged twenty nine, was in the early stage of general paralysis of the melancholic type. I first saw him in May, 1892. The patient's father stated that his memory had been gradually failing for twelve months past, and that he had recently become quite incapacitated for work. I found him in an emotional state crying or laughing on slight or no provocation, and he had delusions of being "shadowed." The physical symptoms of general paralysis were well marked. He could, however, talk fairly rationally and his principal complaint was of a constant aching, burning and pricking pain at the top of the head. He was put under the usual treatment for three months, during which period he had one congestive attack, and in August, as he still complained bitterly of the pain in the head, I prescribed exalgine in the usual dose of one grain repeated several times daily. When he came again he was much brighter, and he gleefully told me that his headache had disappeared after one or two doses of the new medicine and that he had since been free from it. His father confirmed the statement, adding that he had quite ceased to complain of his head. He has continued the medicine off and on up to the present time and has remained free from the distressing headache, for which he professes himself extremely grateful. His incurable disease is naturally pursuing its course and he is gradually becoming more "lost."

CASE 8.—I first saw this young woman, who was twenty four years of age in January, 1892, she having just been removed from a lunatic asylum by her friends in opposition to the advice of the superintendent. I found her strongly melancholic with a tendency to suicide. She was subject to strong emotional outbreaks. I recommended her immediate reinternment in an asylum, but my advice was not acted on and I lost sight of her until August last when she again presented herself. In addition to her former symptoms she then complained of an "awful pain" in the head, which kept her awake at night. Bromide of potassium in ten grain doses proved useless and at a subsequent interview I added one grain doses of exalgine. Within a day or two the pain had become markedly less and she was again able to enjoy a good night's rest. She has since continued the treatment under exalgine alone and she finds that this controls the headache, though her purely mental symptoms are unimproved.

CASE 9.—This case has been under my care since May, 1892. The patient, who was thirty four years of age, had an accident (a fall on the head) twelve years ago, since which time he had been subject to epileptic attacks, which sometimes occurred as often as six times in a single day. Memory had of late begun to fail. The fits were succeeded by very severe headache across the brows. He was ordered bromide of potassium, which did not in the least affect the frequency of the fits or the headache, though given in large doses for a period of not less than three months. The following are the *verbatim* notes from my case book—"Aug. 15th Has been having four and five fits a day and his headache has been unbearable. For the latter he was ordered two-grain doses of exalgine in infusion of quassia three times a day—Aug. 22nd He has only had one fit since his visit on Aug. 15th, and he says this was the best week he has had for months. The headache is much better and he notices a marked improvement after each dose of the new medicine, which he was ordered to continue.—Aug. 29th Has again only had one fit since last visit, but has been told that the fit was a strong one. Is now quite free from headache and has been enabled to resume his occupation." This patient is still under treatment.

Remarks.—In giving notes of the foregoing cases I do so without attempting any explanation of the physiological action of exalgine. It must, however, be something more

than a mere coincidence that so many cases of violent headache should have promptly yielded to the drug even in small doses such as I gave, and thus, in several instances, after the ordinary remedies had failed to produce any effect. I confess that I at first used the drug in the mental cases without much hope, but rather as a *derrière resort* in cases of early melancholia, associated with headache and insomnia, in which other methods of treatment had proved futile—cases which are but too common in the experience of the alienist physician. I did not, of course, expect to benefit the mental condition by means of exalgine, but in all the cases I succeeded in relieving some of the more distressing symptoms—e.g., headache and insomnia. This remark applies with special emphasis in respect of Case 7, in which no idea of a cure could be entertained, but the patient's remnant of life has certainly been rendered more bearable by the alleviation of the intolerable headache. In Case 9, that of the epileptic man, some possibilities seem to be opened up. That the exalgine practically cured the headache there cannot be the least doubt, but it also appeared to lessen the frequency of the fits. That a *curative* is the opinion of the patient and myself in view of the fact that whilst under observation the number of the fits fell from four or five a day to about one a week. He still goes for days without having a fit, which had never been the case previously. It seems to me, therefore, that exalgine may in common with bromide of potassium and borax, possess the power of staying off the fits (in this patient the bromides had proved utterly useless). I am now making further observations with exalgine in the treatment of epilepsy and propose to give the results of the treatment on some future occasion. In the above cases I have not included several in which, after some improvement, I lost sight of the patient, or others where the patient was not seen again after the first visit, though I have heard indirectly that improvement had taken place, rendering further advice unnecessary. Neither have I included patients who were taking other drugs—mercury or the bromides—in conjunction with exalgine. I have never seen any bad result follow the use of exalgine, but I have never prescribed it in larger doses than two grains every four hours. As a general rule, I have found one-grain doses repeated several times daily to be sufficient for my purpose. Cases 6, 7, 8 and 9 were under my care at a hospital. The remainder occurred in my private practice. A convenient way of prescribing exalgine is to order the dose to be dissolved in ten minims or spirit of chloroform, water or some infusion being added to make up the ounce.

Mecklenburgh square, W.C.

THE CHOLERA EPIDEMIC IN RUSSIA.

By FRANK CLEMOW, M.D. EDIN. &c.

NO III.—IN EUROPEAN RUSSIA.

THE epidemic of 1892 entered European Russia as did many earlier outbreaks, mainly, but not entirely through the mouths of the Volga. A second route followed by the disease may be indicated by a line drawn across the Caucasus from Baku to Poti on Don, thence to the southern governments bordering the Sea of Azov and the Black Sea, and to the south-western group of governments known as the Ukraine.¹ A comparison of the dates upon which the earliest cases of cholera occurred in each of the governments marking these two routes shows very clearly that the epidemic spread with much greater speed by the first route than by the second. The immense river array of the Volga formed a channel along which the infection travelled with almost startling rapidity. The earliest case of cholera in the government (not in the town) of Astrakhan occurred on June 13th.² On the 14th the disease appeared in the government of Saratov on the 23rd in that of Samara, on the 24th in that of Simbirsk, and on the 25th cases of cholera were reported in the government of Kazan. The epidemic had thus travelled in a northerly direction, along the course of the Volga, a distance of 1764 versts (nearly 1200 miles) in the space of twelve days. In what may for brevity be termed the south-western branch of the epidemic, the first town to be affected on the European side of the Caucasian frontier was Rostof-on Don, one of the

chief towns in the territory of the Don Cossacks, and situated, as its name implies, on the River Don. Cholera manifested itself here on June 23rd. In the neighbouring government of Kharkof no case was reported until ten days later (July 8th). On July 12th the infection spread to the adjoining government of Poltava. For a considerable period the epidemic travelled no further in this direction. Not until July 23rd was cholera reported from the government of Ekaterinoslav (situated to the south of Kharkof and Poltava, and to the west of the Don Cossack province). On August 3rd the disease appeared in the Taurida (the government which includes the Crimea), on the 8th in Kherson, on the 16th in Kief, whilst it did not spread to the border governments of Bessarabia and Podolia until the 25th and 30th of August respectively. Whilst the infection was thus travelling comparatively slowly along the shores of the Black Sea, it was also passing from Rostof-on-Don in a northerly direction. On July 2nd, only four days later than the occurrence of the first case of cholera at Rostof, the disease appeared in the town and government of Voronezh. Between Rostof and Voronezh is a distance of 610 versts (about 400 miles). The two towns are connected by a line of railway. They are also connected by the River Don, which drains the whole of the government of Voronezh. The Don is navigable by steamer for half the distance between the towns of Rostof and Voronezh and by smaller craft for the remainder of the distance. Communication by the railway is, of course, much more rapid than by the river, the journey taking exactly twenty-four hours. There is evidence to prove that in this instance the railway was the means of conveying the infection. Cases of cholera occurred at stations on the Rostof-Voronezh Railway on July 1st, and on July 2nd the disease appeared in the town of Voronezh. The rapidity with which cholera spread up the Volga was in marked contrast with the comparative slowness with which it followed the course of the Dnieper, if indeed, that river can be said in any way to have formed a channel by which the infection was carried. The Dnieper is almost unnavigable. The wide estuary below Kherson is too shallow to allow of large vessels entering the river from the sea. To the south of Ekaterinoslav the course of the river is interrupted for a distance of seventy versts by a series of falls varying in height from eight to twelve feet. To the north of this the river is navigable with safety only in the spring, in the summer the many and constantly shifting sandbanks render navigation difficult and at times impossible. The earliest case of cholera in any town on the banks of the Dnieper occurred at Ekaterinoslav on July 28th. The first case in the town of Kief, about 350 versts (240 miles) higher up the river is stated to have been on Aug 16th, in the governments of Tchernigof and Mogilef, through which the Dnieper flows the disease appeared on Sept 5th and Aug 30th respectively, whilst in Smolensk, the government in which the river takes its rise, no case of cholera was reported before Sept. 26th.

It will be well to briefly recapitulate these facts. Along the channel of the Volga, upon whose waters almost the whole of the traffic of Central and Eastern Russia is carried during the summer the cholera infection travelled a distance of nearly 1200 miles in twelve days. On the Dnieper on the other hand, a river which is in no sense a great channel of communication, an interval of nineteen days elapsed between the dates of the appearance of cholera in two towns only 240 miles apart, whilst the long period of sixty days separated the dates of invasion by the disease of Ekaterinoslav and Smolensk, distant (by the river) about 600 miles the one from the other. Having traced the epidemic along the Volga as far as Kazan, it will be convenient to continue a brief itinerary of its course beyond that ancient capital of the Tartars. A few versts to the south of Kazan the Volga is joined by the immense stream of the Kama, which drains the three large governments of Viatka, Perm and Ufa. From Viatka the first case of cholera was reported on June 27th from Perm on July 6th and from Ufa on July 18th. From Kazan the main channel of the Volga may be traced to its source through the following governments in the order named: Nijni Novgorod, where the earliest case of cholera occurred on July 7th, Kostroma, first affected on July 18th, Yaroslavl, first affected on July 21st and finally Tver, where the disease appeared on Aug 5th. It is scarcely necessary to repeat here in detail the dates upon which the first cases of

¹ The district known as the Ukraine comprises the six governments of Viatka, Podolia, Kiev, Tchernigof, Poltava and Kharkof.
² As in the previous articles every date mentioned is according to the Old Style.

³ The town of Voronezh lies on a river of the same name at no great distance from the junction of this river with the Don.

TABLE OF THE CHOLERA EPIDEMIC IN THE RUSSIAN EMPIRE TO DEC. 1ST, 1892 (OLD STYLE)

No. in Map	Name of Government or Province	Cases.	Deaths	Per 100 000 Inhabitants (in round figures)		Percentage of deaths to cases	Date of occurrence of first case of cholera.
				Cases	Deaths		
1	Astrakhan*	21,080	10,080	2,404	1,247	—	June 18th

* The epidemic was at an end by Dec. 1st.

† The epidemic was almost but not quite extinct by Dec. 1st. In the remaining governments the epidemic was still active in December.

MAP OF RUSSIA, TO ILLUSTRATE THE INTENSITY OF THE EPIDEMIC OF CHOLERA

The shading represents a varying ratio of cases of cholera per 100 000 of population. The figures apply to names of provinces referred to in the Table on the preceding page.

cholera occurred in each of the remaining governments. They will be found stated, with as near an approach to accuracy as possible, in the last column of the table accompanying this article. The further course of the epidemic may be briefly summarised as follows. Before the month of July was over, nearly all the central governments had been overrun by the disease, which had also appeared in St. Petersburg. On Aug 1st cases occurred in Lublin, one of the ten Polish governments. During August cholera invaded most of the southern and south western governments, and in the north those of Tver, Novgorod, Vologda and Olonetz. During September, October and November all the remaining governments of European Russia were returned as affected by the disease, with the following exceptions: the governments of Archangel, Esthonia (including the important port of Reval) and Kovno; the two Polish governments of Suwalki and Kalisz; and the Principality of Finland. These governments have remained free from cholera throughout the epidemic.

Before leaving this branch of the subject it will be of

interest to compare the speed with which the cholera epidemic of last year travelled with that attained by earlier epidemics. In the first article of this series it was stated that the recent outbreak had spread through Russia with unprecedented rapidity. Unfortunately the records of past epidemics in the regions then under notice—that is to say in Central Asia and Siberia—were not available for the purpose of comparison. But the case is different in European Russia. Thanks to the labours of Dr Archangel'ski, we possess in his invaluable work on "Cholera Epidemics in European Russia during the Fifty Years 1823-72" an exhaustive account of all the previous outbreaks of the disease so far as concerns their course on this side of the Caspian Sea and the Ural Mountains. By the aid of these records it is possible to substantiate the statement just made as to the relative speed of the epidemic of 1892. In 1830 and 1847 years in which cholera followed the same route as it did last

year, the first case recorded in Astrakhan was, by a curious coincidence, on the same date, July 4th, in each year

Table showing the Number of Days which elapsed between the occurrence of the First Case of Cholera in Astrakhan and that of the First Case in each of the Towns named under the Three Years 1830 1847 and 1892

Table showing the Rapidity with which the Cholera spread from Rostof on Don to the South and West in each of the Three Epidemics. The dates, as before, are those of the first cases in each place

Name of town or government.	1830	1847	1892.
Rostof-on Don	Aug 6th.	July 12th.	June 18th.
Kief	62 days later	73 days later	49 days later
Podolia	88 "	81 "	63 "
Volhynia	123 "	131 "	67 "

These figures prove conclusively that the latest epidemic of cholera has overspread European Russia in a considerably shorter period than did either of the earlier outbreaks. They further show that this increased rapidity in the spread of the disease was not confined to its course along the Volga, but was manifested, though to a less striking degree, in its march westward to the Ukraine. In 1830 there were no railways in Russia, in 1847 there were 343 versts of rail way lines, insufficient to affect in any way the spread of an epidemic, in 1892 there were 30,366 versts of line in the Empire, and of these 28,191 were in European Russia. Facility and speed of communication by water have advanced in like proportion. The conclusion appears inevitable that herein is to be found partly, if not wholly, the explanation of the more rapid course of last year's epidemic as compared with that of former years. One feature of the epidemic must not be passed over. In some instances the disease appeared to be carried from one government to another at a considerable distance, and even to obtain no small hold there, before the intervening governments were attacked. Thus, in the Polish government of Lublin a case of cholera occurred on Aug 1st, and during the month of August there were reported from that government 1125 cases and 337 deaths. On Aug 1st the epidemic had travelled in the direction of Lublin only as far as the governments of Ekaterinoslav, Kharkof and Poltava. Between these governments and that of Lublin lie the governments of Kief and Volhynia, which remained free from the disease until Aug 16th and Sept. 3rd respectively, or fifteen and thirty three days later than the date of the first case in Lublin. In like manner cholera appeared at Moscow and St Petersburg on the same date (July 20th), whilst the intermediate governments of Tver and Novgorod were not affected until sixteen and twenty six days later respectively.

Up to the present only the direction followed by the cholera epidemic and the rapidity with which it overspread the country have been considered, without reference to the amount of sickness and death caused by it in the various governments named. In the table on p. 788 will be found the full statistics of the epidemic from its commencement to December 1st (Old Style). The numbers of cases and deaths and the ratio which these bore to the population in every government affected by the disease in European Russia and the Caucasus are there stated. The number of cases recorded per 100,000 inhabitants has been taken as the standard of intensity of the epidemic, and the governments have been arranged and numbered in descending order of the intensity with which they were affected. In order to present more clearly the distribution of the epidemic I have prepared a map of the

country, and have endeavoured to show by a scheme of shading the relative hold obtained by cholera in each of the governments in which there were more than 100 cases per 100,000 inhabitants. It is important to note that, whilst the epidemic was at an end, or practically at an end, in a large majority of the governments of European Russia and in all those of the Caucasus before Dec. 1st there were sixteen governments from which a considerable number of cases and deaths was reported after that date. The most important of these were the governments of Podolia, Bessarabia and Kief, from each of which large figures were returned during December. Notwithstanding the occurrence of a winter of almost unprecedented severity the cholera infection lingered in some few governments throughout December and January, and even into February. According to the latest returns received by the Medical Department (before February 18th) the disease was still present in ten governments, and it may be of interest to quote their names and the figures of the last report. In five of the governments I am able to add the temperatures (average and minimum) of the chief or "government" town during the period covered by the report. For facilities in enabling me to obtain these temperatures my thanks are due to the Secretary of the Meteorological Office.

OBSERVATIONS ON THE PREVALENCE OF TYPHOID FEVER IN THE GARRISONS OF LOWER EGYPT

By SURGEON COLONEL ALBERT A. GORE

WITH reference to the recent interesting contributions on this subject in THE LANCET, conditions of soil have undoubtedly much to do with the prevalence of typhoid fever. At a lecture given in the Sanitary Institute, Dublin, on March 18th, by Sir Charles Cameron, he gave it as his opinion that the distribution of typhoid fever there depended altogether on conditions of soil saturated with matters of a most objectionable character. It is well known that regiments newly arrived in that garrison have suffered from time to time a good deal from enteric fever. In thirteen years, 1872-84, the French army was composed of a total effective of 3,375,409 men, yielding 151,319 cases of typhoid fever and losing from that disease 17,642 men, or 14.76 per cent of the cases treated—a third of the total mortality of the army. With regard to sanitation M. Brouardel writes "The number of soldiers attacked by typhoid fever is always relatively more high than that of the inhabitants of the towns which they are sent to garrison. The young men taken for military service are about the same age as those who are most often attacked with typhoid fever. They are in the same condition of non-acclimatisation in their new domiciles, they are equally sensible of typhoid fever, and we can consider them as the precise test of the salubrity of the towns. In a town where typhoid fever is endemic, when acclimatised to the plague, it acts by degrees on the greater number of the inhabitants, but import all of a sudden a group of young men not having been under the same influences, and we cause in them a veritable epidemic. The aptitude for contracting the disease is five or six times greater among the military on account

of age and the non acclimatisation indicated before. The most absolute law is that the mortality in the army by typhoid fever permits one to judge of the salubrity of a town.¹ To the fouling of the subsoil in India is attributed much of the typhoid fever which prevails, which insanitary condition of soil infects the air and water. When this condition in Europe has had such a powerful influence on the French Army, it is not to be surprised at that in such towns as Cairo and Alexandria (where to the local insanitary conditions the debilitating influence of heat on the nervous system is super-added) young and unacclimatised soldiers should suffer in a greater degree than the inhabitants. Sir James Hanbury, after the campaign of 1832, when out of an average strength of 13,465 (July 17th to Dec. 31st), the disease caused 575 admissions and 223 deaths, very aptly summed up the situation in the following words—"To describe its genesis to any one specific cause would not, I think, in this case be justified by reason or experience. The causes were multiple, but one of the most potent, in my opinion, was the exposure under canvas on ground in the neighbourhood of a large city whose conservancy arrangements were on the most primitive system, and the filthy habits of the lower classes acting on a body of men lowered by the privations hard work and exposure in a campaign during the hottest and most unhealthy season." This large body of men, it will be recalled, was of the most hable age, and undergoing that constitutional change commonly called acclimatisation. During 1833-84 and 1835 several regiments suffered severely from enteric fever in Ramleh Barracks which, when taken over on being evacuated by Arabi's troops in 1882, were in a very filthy condition, as was the vicinity. They were built on rubbish, into which the leakage from drains and cesspits as also from the stables had soaked, rendering apparently the site inherently unhealthy by contamination of the sub-soil. Referring to them in 1884 Brigade-Surgeon Ramsbottom writes "This localisation seems to indicate that it is not to the water supply of the town that we must look for the causation of the disease, but other causes, and the conclusion arrived at is that the chief cause to be assigned for the prevalence of fever in these barracks must be looked for in the saturation of almost the whole of the soil underneath them by sewage matter in past years, caused by cesspits and drains being built without inverts the bottoms being thus left open and allowing the sewage to percolate the soil." With regard to contamination of the air the following note appeared in the *Egyptian Gazette* of May 20th, 1889 the very month when fever was beginning to show itself. "The attention of the sanitary authorities is directed to the pestilential exhalations emanating from the sewers in the Ramleh Boulevard, Alexandria, and its neighbourhood. Too much vigilance cannot be exercised at this season of the year in all matters affecting the public health."

The question of water supply and its influence depends upon whether it is filtered or unfiltered apparently. When enteric fever first appeared among the troops at Ramleh in 1832 it was attributed in the first instance to the use of well water fouled by adjacent compounds in each of which was a cess-pit without invert, made of loose rubble, seldom emptied and so allowing the sub-soil to be thoroughly saturated with liquid sewage, which of course percolated into the wells. A contributor to one of the medical journals at this time wrote "The fresh water canal close by was polluted with filth as if by design." Later on it was recommended by the Principal Medical Officer of Alexandria (Deputy Surgeon General Fox) that the water should be boiled before being filtered, and for this purpose appliances and an allowance of fuel were granted by the military authorities. The Mahmoodeveh, or sweet-water canal, taps the Rosetta branch of the Nile at Atfeh, fifty miles from Alexandria. It receives many impurities. During 1833 no less than 472 human corpses were found in the Nile from which it springs and on Feb. 1st, 1839 appeared the following paragraph in the *Egyptian Gazette* with reference to the canal. In consequence of the many complaints received from the inhabitants of Alexandria and from Mr. Cornish, the manager of the Alexandria water company as to the bad quality of the water now obtainable from the Mahmoodeveh canal for consumption in town, his Excellency Riaz Pasha has requested the Minister of Public Works and the Director General of the Board of Health to appoint a Commission entrusted with the immediate examination of the question and with powers to report as to the measures that should be taken to improve the Alexandria water supply.

This Commission recommended 'that all drains running into the canal from the villages along its banks should be closed, and that fresh outlets for the drains should be made to discharge on the canal side, that strict orders should be given to the inhabitants along the banks to cease making the canal the receptacle for every description of filth and rubbish, and that these orders should be enforced by severe punishment in case of their being disregarded, that carcases of animals should be promptly removed when seen in the canal, that the canal should be systematically patrolled under the direction of the Irrigation Department who on their part would open the lock at Kafr Dawar once every ten days in order to allow a good flash of fresh water to come in from the Katetbeh canal.' That unfiltered water of this description, or water obtained from wells in the lower quarters of Alexandria, is made into "ginger pop" and other drinks and purchased by soldiers, is very probable. But with regard to the filtered water a medical officer was sent from Cairo to make an analysis of this when enteric fever was very prevalent in Ramleh Barracks. He reported "that it contained a small amount of chlorides, a low percentage of fixed and volatile solid and freedom from hardness—characters, on the whole of a pure and wholesome water with no signs of sewage contamination." That the germs of enteric fever may be carried from one station to another is proved by the fact that the troops which went from Ramleh to Cairo for the review carried them with them and for three months after leaving Egypt cases continued to occur in regiments which left the command. At intervals cases were admitted from H.M. ships in harbour the crews being healed by drinking condensed water on board. These have been very few and were probably contracted on shore when the men were on leave.

Temperature has a considerable influence as a rule. The mean air temperature is at its minimum in January and rises gradually during February, March, April and May, but much more quickly in June and July when at Cairo it reaches its maximum. The Nile rises rapidly in August and reaches its maximum in September falls somewhat in October and then more quickly subsides. With its rise the mean air temperature commences to fall. In the years 1833-69 inclusive, the ratio per 1000 of admissions for enteric fever in the Egyptian command increased with the temperature, was highest in May and June and lowest in December. At Alexandria it is most prevalent in the autumnal and damper months of August, September, October and November. Milk in Egypt is systematically adulterated with water and much of it is obtained from the buffalo a filthy feeder. As long as the nomenclature of diseases is worded as at present many cases of enteric fever will be included amongst the recorded under the heading 'Simple Continued Fever' defined as a simple fever with no distinguishing characteristics. Many of the cases are of twenty-one days duration or longer with a curve of temperature very similar to that of typhoid fever but with no diarrhoea, rose spots or enlargement of the spleen. It cannot be forgotten that with reference to these Liebermeister has written "The diseases produced by the specific poison of typhoid fever differ a good deal among themselves. Some are so serious that life is almost inevitably destroyed, others so trifling that patient and physician are left in doubt whether there was disease at all. Between the two extremes at every gradation the lighter cases are often called a febrile or febrile abdominal catarrh, gastric fever &c. a custom practically not unjustifiable, and in numerous epidemics the imperfect cases are more common than the perfect ones." The well known rule that the greatest predisposition is between the ages of fifteen and thirty years has been amply verified by the medical statistics of the army in Egypt. Of 119 fatal cases recorded at Alexandria from 1833 to 1839 inclusive, only 2 were over thirty years of age, and of the whole only 16 exceeded twenty-five years. Many cases were imported by regiments from "up Nile" and Saakin, and did not originate at Alexandria, and during this period the more acclimatised regiments and smaller units in the garrison suffered least. There were several admissions for ague, the greater number imported but several of these originated in the muckety camp at Melk until removed from the site overlooking the marshy banks of Lake Mariout. Nearly all the cases of remittent fever were from Cyprus or other Mediterranean stations. Of late years since the water of the canal has filtrated into the sub-soil at Suez and Ismailia, intermittent fever has been more common at those stations.

The shore about Alexandria is fouled by filth of all kinds and many drains open on to it. During the high winds of winter seaweed is thrown up and with the summer heat

¹ La Semaine Médicale Dec. 12th, 1833.

decays and gives rise to very unpleasant odours. Owing to some pandemic cause or seasonal influence some years are more unhealthy than others, and some summers are cooler, and there are differences in the internal economy of regiments which influence their respective health rates.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL AND THERAPEUTICAL

AN ILLUSTRATION OF THE ADVANTAGES OF THE CRÉDÉ METHOD IN THE PREVENTION OF OPHTHALMIA NEONATORUM

By WALTER W. HEBLAS, M.R.C.S., L.R.C.P. LOND.,
HOUSE PHYSICIAN, GENERAL LYING IN HOSPITAL, LAMBETH

I AM indebted to Dr. Herman and Dr. Cullingworth, under whose care the patients were, for permission to publish the following notes.

The excellent results to be obtained from the Crêdé method for the prevention of ophthalmia in new born infants are exemplified in the following brief notes of an outbreak so out short in the wards of the General Lying in Hospital. The method consists in dropping a two per cent solution of nitrate of silver into the eyes immediately the head is born. Up to the time of the outbreak the usual method of treating the eyes in this hospital had consisted in wiping them with clean cotton wool as soon as the head was born (the wool being immediately afterwards burnt). A few drops of perchloride of mercury solution (1 in 2000) were dropped in each eye after birth, and this was repeated twice a day during the fourteen days the infant remained in the hospital, and every mother had a vaginal douche of Condy's Fluid (half an ounce to the pint of water) previously to delivery. At the end of last and at the commencement of this year numerous cases of ophthalmia occurred in the hospital for which no cause could be found. From Jan. 1st to 22nd out of seventeen children born alive seven were so affected, this being more than 42 per cent. On the latter date the Crêdé method was put in force. Not one single case occurred afterwards. The treatment gives rise to inflammation of the conjunctiva with an abundant thin muco purulent discharge, commencing a few hours after the application, in nearly every case, however, this completely subsides in from four to five days, when the eyes regain their normal appearance.

EPIDEMIC INFLUENZA AND DRAINS

By AUGUSTUS H. BAMPTON, M.D. RUI

THERE is considerable evidence accumulating of a nature to force one to the unpleasant conclusion that influenza has become endemic amongst us, and the assurance of epidemiological prophets that, as in former times, the epidemic would be only of three years' duration has been weighed in the balance of experience and been found wanting. To me it has always been a belief that influenza is as likely to be always with us as any other of the zymotic diseases. The problem I offer for solution to my professional confrères is, Where is now the lurking place of the germs of this disease? I venture to suggest that the most probable habitat and favourable environment would be the drains. And my reasons for thinking so are based upon the facts that in badly drained houses I have noticed that first one member of a household and then another member are continually down with the complaint, and this in spite of isolation and disinfection, that where the drains have been made air tight the attacks cease, also in well drained houses influenza is absent. It may be urged that sewer air only renders the individual exposed to its baneful influence more susceptible to attack by lowering the general health. That may be true in part, but it does not explain away the influenza germ, nor does it help in the solution of the problem. In conclusion, where influenza never seems to be out of the house I say, "Look to the drains."

UNIVERSITY COLLEGE HOSPITAL

A CASE OF TORSION OF THE SPERMATIC CORD, WITH STRANGULATION OF THE TESTICLE

(Under the care of Mr. A. E. BARKER.)

WE publish below the notes of another of the rare and interesting examples of strangulation of the testis due to twisting of the epididymis in which the symptoms were those of strangulated hernia. We have previously presented our readers with reports of similar cases under the care of Mr. Whipple, Mr. Bryant and Mr. Page, and have referred to others. A boy aged sixteen, under the care of Mr. Whipple¹ in the Plymouth Hospital, had sprained himself the day before admission, when a swelling in the left groin was present, and he gave a history of vomiting. The swelling was hour glass shaped. "The lower half of this was the left testicle lying in the upper part of the scrotum, the upper, lying over the external abdominal ring, about the size of a hen's egg, was very tense, dull on percussion, and gave no impulse on coughing." In this case the epididymis appeared to be twisted twice on its own axis, and there was an ommental hernia, the piece of omentum being attached to the testis. The testis was removed. Mr. Page's² case was that of a lad aged seventeen, admitted for urgent symptoms presumably in connexion with a right congenital inguinal hernia for which a truss had been worn. The symptoms commenced three days before admission, with severe local pain, tenderness and swelling. He vomited once and had constipation. The temperature was normal. Operation proved the symptoms to be due to gangrene of testis after twisting of the cord, two turns to the right, at the external ring. The open funicular portion of the peritoneum was closed by ligature and the boy made a rapid recovery. Mr. Bryant's case was that of a boy aged fifteen, who had been suffering from symptoms supposed to be due to strangulated hernia. Three half twists made inwards completely untwisted the cord. The testis was not removed but afterwards wasted. Mr. Barker also reminds us of two others, one under the care of Dr. Keen (referred to by Mr. Bryant), that of a man aged twenty three, the subject of an undescended testicle and reducible inguinal hernia on the same side. The cord had made three half turns, the testis was removed. The other, under the care of Mr. Davies Colley, was that of a boy aged fourteen, with undescended testicle, but no hernia, in which the cord was twisted outwards three turns. The testicle was not removed, but the cord was untwisted. This testicle sloughed. We have purposely limited our references to cases in which the retained testis had become inflamed in consequence of a twist in the cord, and excluded those cases, much more common, in which an injury has produced the symptoms and in which no such twisting of the cord has been met with, although the symptoms produced were similar.

A healthy lad aged fifteen stated that the right testicle had been always small and had never fully descended into the scrotum, and that he had had a rupture on the same side since he was seven years old. This rupture disappeared until about one year ago and since then had usually been down to the top of the scrotum when he was in the erect position. He had never worn a truss. On March 2nd, 1893, the bowels were moved and soon afterwards the "rupture" came down as usual, but could not be reduced. He was at work throughout the nights of the 2nd and 3rd. On the latter day he was sick twice, but was at work again at night, although the swelling was increasing in size and becoming painful, he was sick twice again on the 4th. On the 5th³ he took to his bed and remained there until admission into hospital on

¹ Reported by Mr. Nash. THE LANCET May 16th 1891

² THE LANCET, July 30th 1892.

³ Under the advice of his medical attendant Mr. Hereward Wake

the 9th, the lump becoming more and more swollen and tender. On admission on the 9th he looked well, the tongue was dry along the dorsum and furred, the pulse was 96, temperature, 102.2°. The right testicle could be felt about two inches below the external abdominal ring, swollen many times beyond its usual size, which the patient described as about that of the last joint of the little finger. Above this there was a large oval swelling occupying the position of the inguinal canal and reaching nearly to the testicle. This swelling was hard and tender, and the skin over it was dark and oedematous. There was no abdominal tenderness. He had passed flatus every day since the onset but the bowels had not been moved since the 2nd. Regarding the case as one of strangulated omental hernia, Mr Barker operated at once in the usual way. On opening what appeared to be the sac of a hernia, just external to the ring a quantity of bloody serum with some clots escaped, and a dark livid mass was exposed, smooth on the surface and very tense. At first this was regarded as a knuckle of strangulated intestine, but a few moments later it was recognised as the testicle twisted on the cord outwards three half turns and consequently strangulated. There was no hernia down at the time. A twist of three half turns inwards undid the strangulation but as the organ was much damaged the cord was divided and the organ was removed. The canal was then stitched up and the wound was closed without drainage. The patient made an excellent recovery. The wound was left untouched until the ninth day, when union by first intention had taken place. Around two or three of the stitches the skin had slightly inflamed owing to the oedematous condition of the tissue at the time of operation. The temperature fell to normal after the latter.

Remarks by Mr BARKER.—These cases are probably not quite so uncommon as the literature of affections of the testicle would lead one to infer, but have possibly been overlooked and treated as inflamed incarcerated herniæ in the past. I can find only four similar cases recorded, but have heard of others. Of the four appended almost all showed the same features. They all occurred in young individuals who had imperfectly descended testicles on one side. The symptoms closely resembled those of strangulated hernia—i.e. sudden onset pain, vomiting, constipation and increasing swelling. Some were actually associated with hernia. The cause in more than one appeared to be an attempt to reduce the hernia causing torsion of the testis or the cord. In all an operation was performed with recovery. In two the testicle was not removed, and in one of these it subsequently sloughed away, in the other, though the wound remained healed, the organ underwent complete atrophy. In Dr Keen's case organisms were cultivated from a hematoma found round the epididymis. The proper treatment appears to be removal of the testicle in all cases and suture of the inguinal canal so as to radically cure the hernia. To leave the testicle in the scrotum after untwisting the pedicle would probably result in most cases, as in two recorded either in atrophy of the organ or in its subsequent sloughing away.

YORK COUNTY HOSPITAL

AMPUTATION AT THE HIP JOINT FOR SARCOMA OF THE FEMUR—STRANGULATED HERNIA WITH UNUSUAL SYMPTOMS.

(Under the care of Mr JALLAND.)

THE case of hernia presents unusual characters, the symptoms being irregular and not unlike those met with in partial enterocoele. The exact nature of the hernia is not quite clear, but from the description we incline to the opinion that it was a congenital one with a small opening, for intestine was felt and displaced from the neck of the hydrocele sac. The intestine was also slightly adherent, but how long it had been so it is not possible to say. How much disturbance may have been due to the escape of inflammatory fluid from the acute hydrocele into the peritoneum through the small opening which was apparently blocked at the time of operation, is a matter of conjecture. There can have been no severity of strangulation, such as would have resulted in ulceration or sloughing of bowel, for the after treatment of the case was unmarked by complication.

The case of periosteal sarcoma of the femur illustrates the exceeding malignancy of these growths and the unsatis-

factory result of the severe measure of treatment which at the present day is apparently the best at our disposal. It is not always easy to determine the nature of the disease from which the patient is suffering when complaint is made of the knee, especially if the disease commenced close to or has invaded the interior of the joint, and should the surgeon have come to a diagnosis as to the probable nature of the case and recommend exploration, to be followed by operation, it is difficult to make the friends understand that there is any urgency in the case, and that operation must not be delayed if even a moderate success is to be obtained. Continued experience only confirms the statement of Mr Butlin, that amputations performed for this disease are very dangerous to life, rarely affording a permanent cure or giving long relief. Of thirty six cases collected by him, in six the disease recurred in the stump, seven died of secondary disease, nine died from operation, ten were lost sight of, two died from unknown causes and the remainder were alive and well more than twelve months afterward. Berck¹ collected 118 cases, recorded in the literature of disarticulation of the hip-joint for malignant disease of the thigh. Of these, 36 had been fully recorded and 27 died of secondary growth within from four weeks to four and a half years. He found no case of lasting cure. Mr Rose has recorded a case in which after amputation at the hip there was no recurrence for five years. For the notes of these cases we are indebted to Mr J B Lendrum, M B, house surgeon.

CASE 1. Sarcoma of the lower end of the femur, amputation at the hip joint, recovery, subsequent death from secondary growth in the lungs.—A girl aged sixteen was admitted into the York County Hospital on Oct. 6th, 1892, for what was supposed to be a white swelling of the right knee joint. The history was as follows. The patient had been a stout, healthy girl of about eight stones in weight and had never suffered from any serious illness. In March last she began to feel an aching pain in the right knee. This pain went on for three months without any visible alteration in the joint, but then the knee began to enlarge and the pain to increase, being specially bad at night. Three weeks after the enlargement set in the patient fell on the knee. She was under treatment for tumor albus and in the latter end of August a Thomas's splint was applied and she took to her bed.

On admission the patient was a thin, cachectic looking girl, very anæmic. On the right lower extremity was a Thomas's splint the hip ring of which had to be filed through and bent to allow of its being taken off the limb. There was a large boggy swelling in the region of the right knee-joint, commencing gradually five inches above the centre of the patella and ending suddenly at the level of the tubercle of the tibia. This tumour was apparently arising from the lower third of the femur. The condylar portion of the femur was enlarged in all directions and the skin over the tumour was very discoloured—i.e., red purple in patches over the outer posterior and inner surface of the joint. There was a slight softening on the inner side of the knee. Below the level of the tubercle there was great swelling and oedema of the leg and foot. The glands of the groin were slightly enlarged. The following were the measurements—

	Right.	Left.	Difference
From the anterior superior spine to the external malleolus tip	31½ in.	33 in.	1½ in.
Circumference 4 in. above the centre of the patella	18½ in.	11½ in.	7½ in.
Circumference at the level of the condyles	19½ in.	11½ in.	8 in.
Circumference at the tubercle of tibia	14½ in.	10½ in.	4½ in.
Circumference just above the ankle	10½ in.	8 in.	2½ in.

In five days after admission the circumference round the right knee increased ½ in., in seven days 1½ in. and in twelve days 2½ in. An exploratory aspiration was made but only blood and some large round cells containing several nuclei were seen under the microscope. The patient's average temperature till operation was 99.6 F and pulse 120. On Oct. 18th under ether, disarticulation of the right hip was performed by the Furneaux-Jordan method. The temperature rose in eight hours after the operation to 102, but in twelve hours it became normal and remained so. The first dressing was done four days after the operation, and then every five or six days for some time, when the wound had healed by first intention, excepting at the upper part of the perpendicular

incision, where some serum from the joint continued oozing out, this eventually completely healed. The patient was quite well and able to leave the hospital by the middle of December, but stayed for Christmas to be present at the Christmas tree entertainment.

Towards the end of December she had symptoms of pleurisy on the right side. The chest was tapped with a fine aspirator, but only a small quantity of blood stained fluid was drawn off. From this time the girl began to fail, losing flesh, and the chest trouble was evidently spreading, the left side becoming affected, until she died on Jan 24th, 1893.

At the post-mortem examination permission was only given to examine the chest. Both lungs were found to be infiltrated throughout with the growth, which also involved the pleura and the mediastinal glands. Under the microscope it presented the same appearance as the primary tumour, a very round celled sarcoma, amongst which was interspersed some cartilaginous tissue.

CASE 2 Strangulated hernia, operation, recovery—A man aged twenty one was admitted into the York County Hospital on May 30th, 1892. He had been attended by a private practitioner, who had reduced a right inguinal hernia, but on examination I found a tumour in the inguinal canal still left. Three weeks before this the patient had had gonorrhoea. The bowels were moved six hours before admission.

On admission the right testicle was swollen and tender, there was a large swelling in the right side of the scrotum and the inguinal canal up to the internal abdominal ring. This was dull on percussion and no impulse was felt on coughing. The patient had been vomiting a bile stained fluid before admission. On May 31st towards the evening sharp pain was felt in the right iliac region and across the abdomen. Vomiting occurred during the day of a copious quantity (about two pints) of bile-stained fluid containing what seemed to be intestinal casts of curdled milk enveloped in casein. The patient had not drunk two pints of fluid since admission. On June 1st he suffered most acute pain, and the sickness continued, with similar ejections, the bowels acted and flatus passed. The temperature rose in the evening to 101°. The next day the bowels acted again, some pain and sickness being complained of. The temperature in the evening was 99°. On the 3rd the bowels acted again and flatus passed. Temperature 98.2. For the next two or three days there was no action of the bowels and things remained much the same. The swelling in the scrotum and in the inguinal region, which was diagnosed to be fluid, was decreasing. On the 5th the patient vomited twice a large quantity of peculiar pea soup-like fluid after drinking some milk. No action of the bowels had taken place since the 3rd, but flatus was passed daily. During the night of the 6th the patient vomited five times, the vomit being distinctly faecal in character, and when the nurse was out of the ward he walked to the closet, when the bowels were slightly moved. The abdomen was very swollen and the pain very acute.

On the 7th Mr Jalland, in the middle of the day, the patient being under ether, cut down upon the swelling in the inguinal canal, which proved to be, as was expected, an acute hydrocele of the tunica vaginalis, extending almost up to the abdominal ring, and an enlarged testicle, but no bowel was contained in it. At the upper limit, however, the finger could just feel a small piece of bowel, evidently only a portion of the calibre of it, which with very little pressure vanished into the abdomen. This was thought to be the hernia, as nothing else was found. The wound was stitched up and a small drainage-tube introduced into the lower end. After the operation the same day, the bowels were moved five times. During the next day the temperature rose to 102.6 and three motions were passed. In three days the temperature became normal, the wound was dressed and found to have united by first intention except at the site of the drainage tube, which was then removed. During the next seven days the symptoms had all abated, the wound was comfortable the bowels were moved once by an enema. On June 17th great pain was felt round the umbilicus, and the patient could not straighten his legs on this account, but lay with his knees drawn up. Next day, after an enema, the bowels were moved and the temperature then rose to 101°. He then had diarrhoea for one day, after which the temperature fell and the patient made an uninterrupted recovery, only a slight febrile attack on each attempt to get up on July 12th and left the hospital on July 17th.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY

Resection of Intestine and Immediate Suture in Cases of Gangrenous Hernia

An ordinary meeting of this Society was held on March 28th, the President, Sir Andrew Clark, in the chair.

Mr KENDAL FRANKS read a paper on Resection of the Intestine and Immediate Suture in cases of Gangrenous Hernia. He related the case of a woman aged thirty who had an umbilical hernia of three months' duration. It became strangulated on Sept 22nd, 1891. Thirty hours and a quarter afterwards herniotomy was performed. The abdomen was found to be full of gelatinous fluid associated with an ovarian tumour. The loop of intestine proved to be gangrenous. Nine inches and a quarter were excised and the ends of the intestine immediately united by means of Gily's suture. The abdominal cavity was closed, and a glass drainage-tube inserted, but was removed on the fourth day. The bowels acted regularly after the fifth day and recovery was complete. Five weeks later the abdomen was again opened, and the ovarian multilocular semi solid cyst was removed. The sutured intestine was inspected, the union was perfect, the line of union could be felt as a thickening in the gut, but could not be detected by the eye. Mr Franks discussed (1) the co existence of ascites with strangulated hernia, and (2) the treatment of gangrenous hernia. The various methods of treatment were reviewed, and the following were some of the conclusions arrived at. Gangrenous hernia might be treated on one of two principles, either by resection and immediate suture or by the formation of an artificial anus. The latter necessitated a secondary operation for its cure either by the use of Dupuytren's enterotome, or by secondary resection and suture. To estimate the relative merits of these two principles of treatment, the death rate of immediate resection and suture must be compared with the death rate following the formation of an artificial anus, plus the death rate of the secondary operation required for its cure. The death rate in cases of gangrenous hernia treated by the formation of an artificial anus was 80.7 per cent. The death rate of secondary resection and suture for the cure of artificial anus was 38 per cent. The death rate following the use of the enterotome was 7.3 per cent. The mortality which attended resection and immediate suture in gangrenous hernia was shown in a table, presented to the Royal Medical and Chirurgical Society of 220 published cases to be 48 per cent. Mr Franks concluded that intestinal resection and suture should be the operation of choice in gangrenous hernia, and that simple enterotomy followed by the formation of an artificial anus, should be reserved for absolutely special cases and should be considered as an exceptional procedure.

Mr JONATHAN HUTCHINSON, jun, mentioned a case of a woman aged forty who had had a strangulated hernia for three days. On opening the sac he found the included portion of the gut gangrenous, and there was commencing peritonitis. He then opened the abdomen in the middle line removed altogether twelve centimetres of the intestine, and having taken care to be well away from any damaged portion. The piece removed was shown to the Society and exhibited clearly where the gut had been gripped in the strangulation and some two inches on either side. He had not found clamps of much use and preferred the fingers of an assistant for this purpose. He had used a continuous suture for the mucous membrane and Lembert's suture of fine silk for the rest of the wall in joining the ends of the intestine together. The sac was removed at the first opening and so a radical cure was performed. The patient made an uninterrupted recovery. In this case, although no taxis had been attempted, inflammatory changes above the seat of the stricture had set in. The mucous membrane was ulcerated quite through and there was commencing peritonitis. One question in these cases was whether the section through the intestine should be oblique in order to prevent stricture. In his opinion this was not necessary. Another question was whether the resection could be performed at the site of the hernia or through an opening in the middle line. He was in favour of the

latter plan, as after suture the thickness of the gut was increased, and it might be difficult or even impossible to return it through a femoral or even through an inguinal ring.

Mr LOCKWOOD said that surgeons up to the present appeared to have been averse to accept resection, their objection being based on statistical grounds. He agreed with Mr FRANKS that resection was an ideal operation. He preferred resecting the intestine through the original wound and cutting through Poupart's ligament if there was any difficulty in replacing the sutured gut. He considered that method of suture the best with which the surgeon was most familiar.

Mr A. E. BARKER emphasised the importance of removing enough mesentery and intestine to insure having healthy tissues to suture together. He preferred to resect through a median incision, as greater freedom for manipulation of the mesentery and intestine was allowed. The plan that he advocated was to remove all the gangrenous parts through the hernial wound and to close temporarily with ligatures the ends of the intestine and then resect them through a median incision. With reference to statistics he suggested that when an artificial anus was made the cases were very desperate, enterectomy being performed in the more favourable ones.

Mr BOWLBY agreed with the position that Mr FRANKS had taken up though he thought that he had perhaps taken a too favourable view of the operation. From statistics gathered from St Bartholomew's, Guy's and St Thomas's Hospitals by Mr Berry over a period of ten years, it appeared that the mortality for all cases of strangulated hernia operated upon was 44 per cent. on 946 cases. The statistics for St Bartholomew's Hospital, which he had himself collected showed a mortality of a little over 40 per cent. Mr FRANKS statistics for resection were almost as good and the explanation of this was probably that unfavourable cases had not all been recorded. It was remarkable how many times some of the surgeons mentioned by Mr FRANKS had performed this operation of resection, as out of the enormous number of cases of hernia admitted into St Bartholomew's Hospital in the last ten years, in only forty two was the intestine gangrenous. It might be inferred, therefore, that resection had occasionally been performed in cases in which the intestine was not gangrenous.

Mr THOMAS SMITH agreed with Mr Bowlby that the term "gangrenous" conveyed a different meaning to different operators. The great obstacle to the operation was the depressed condition of so many of the patients, which rendered them unsuitable subjects for so prolonged an operation. He did not approve of the use of Senn's plates in these cases. He added that in every case of artificial anus a further operation was not always needed, as occasionally they tended to recover without interference.

Mr CLEMENT LUCAS said that in resection in cases of femoral hernia one question which would have to be settled sooner or later was whether the operation should be completed at the seat of the hernia or through a median incision.

Mr FRANKS in reply stated that he had found the fingers of a capable assistant to be the best form of clamp, that an oblique section was the proper one and that more should be taken from the convexity than from the concavity, and that if the condition of the intestine was doubtful it was better to remove the doubtful part than to risk returning a gangrenous portion into the abdomen. A plan adopted by German surgeons was to fasten the doubtful portion to the abdominal wall and to watch it for twenty four hours, and then to resect or return it according to circumstances. He said that apparently large pieces of intestine could be removed without doing any harm to the patient and without increasing the risk but that it was very dangerous to leave or suture any unhealthy tissue. In cases of femoral hernia he preferred to open the sac and to clean the parts and then to resect them through a median incision. With regard to sutures, he had always adopted Gily's plan up to the present, but in future intended to use the continuous method. The mortality was probably about 56 per cent which was much lower than in cases of artificial anus. He referred to a case of colectomy for malignant growth which he had published in the Society's Transactions for 1889 and stated that the patient was at the present time alive and well.

The PRESIDENT observed that the duration of time needed for the operation of resection had not been, he thought adequately discussed and that, from a physician's point of view, it was a very important one.

OTHER METROPOLITAN MEDICAL SOCIETIES

HARVEIAN SOCIETY OF LONDON.—A meeting of this Society was held on March 23rd, Mr Malcolm Morris, President, in the chair.—Dr H. A. CALEY read a paper on a case of Simple Ulcerative Colitis, the patient recovering after a long illness. It presented severe constitutional symptoms, those of toxæmia and exhaustion, together with local symptoms (tenderness, bleeding, diarrhoea), clearly referable to extreme ulceration of the large intestine.—Dr SIDNEY PHILLIPS said that six cases had come under his own observation at the bedside or in the post-mortem room. There might be no mælena throughout, though the intestine was deeply ulcerated and perforations had occurred. Perforation might take place with no pain or signs of collapse, and feces might pass into the peritoneal sac for days before death.—Dr SOLOMON SMITH said that in his experience mæla, in consequence of the copious stools to which it gave rise, was far from being a form of diet which gave rest to the colon. It appeared to him that in cases of ulceration hæmorrhage was far more likely to be produced by stretching and distension of the intestine by the gases of decomposition than by mere movement.—Dr ALDESON stated that in cases occurring in children he had found nitric acid with very minute doses of opium useful.—Dr BOXALL remarked that ulcerative colitis was the main feature of mercurialism occurring as the result of sublimate douching in obstetric practice. The symptoms present in most of the cases which had come under his notice were abdominal pain and distension, diarrhoea, tenesmus, with mucus and blood in the stools, and little or no fever, but the more generally recognised evidences of mercurialism, such as salivation, loosening of teeth line on the gums and metallic taste were usually either entirely absent or but slightly pronounced. It was highly essential to bear this in mind and on the first indication of symptoms to stop the use of the mercury to prevent further absorption and to promote speedy elimination. He had been present at the necropsy of two cases in which mercurial douching had been persisted in under the impression that the symptoms betokened septic poisoning. On examination the colon was in each case found to be inflamed and studded with numerous ulcers, especially in the region of the ileo cæcal valve, and in one spot in the more advanced case was actually necrotic and bordering on perforation.—Mr PENTON BEALE asked whether any bacteriological examination had been made.—Dr CALEY replied.—Mr TREVES discussed the Pathology of Typhilitis and certain points in its clinical aspect. He pointed out that the majority of cases of typhilitis recover under medical treatment and that only a certain proportion of the cases of relapsing typhilitis call for operation. Before operating in the relapsing form one or other of the following conditions should be present (1) The attacks are numerous, (2) they are increasing in frequency and severity, (3) the last attack has been alarming, (4) the patient is rendered an invalid, (5) there is evidence of pus about the vermiform process, (6) in every case the enlarged appendix should be capable of being demonstrated during the quiescent period. Mr Treves then described the details of the operation and concluded by giving a description of fourteen cases of removal of the appendix for relapsing typhilitis which had been under his care all of which recovered.—Mr EASTES considered that the cases usually seen by the members of that Society were of a less serious character than those described by Mr Treves, but that the treatment required for those milder cases was equally definite and should consist of absolute rest in the recumbent posture, semi-starvation, liquid diet alone, and the use of an opiate with some belladonna to prevent constipation.—Mr CRIPPS LAWRENCE mentioned having treated cases, one some six years ago, with anti rheumatic remedies with marked benefit. In an experience of some years, including a fair proportion of cases of typhilitis in various forms he could not recall any that had necessitated operation.—Dr SOLOMON SMITH Dr SIDNEY PHILLIPS Dr WILLIAM HILL and Mr HUBERT PHILLIPS also took part in the discussion.—Mr TREVES replied.

ISLINGTON MEDICAL SOCIETY.—At the last meeting of this Society Dr ALEXANDER MORISON read a paper on the Causes and Treatment of Dilatation of the Heart, in which he con-

incision, where some serum from the joint continued oozing out, this eventually completely healed. The patient was quite well and able to leave the hospital by the middle of December, but stayed for Christmas to be present at the Christmas tree entertainment.

Towards the end of December she had symptoms of pleurisy on the right side. The chest was tapped with a fine aspirator, but only a small quantity of blood stained fluid was drawn off. From this time the girl began to fail, losing flesh, and the chest trouble was evidently spreading, the left side becoming affected, until she died on Jan 24th, 1893.

At the post-mortem examination permission was only given to examine the chest. Both lungs were found to be infiltrated throughout with the growth, which also involved the pleura and the mediastinal glands. Under the microscope it presented the same appearance as the primary tumour, a very round celled sarcoma, amongst which was interspersed some cartilaginous tissue.

CASE 2 Strangulated hernia, operation, recovery—A man aged twenty one was admitted into the York County Hospital on May 30th, 1892. He had been attended by a private practitioner, who had reduced a right inguinal hernia, but on examination I found a tumour in the inguinal canal still left. Three weeks before this the patient had had gonorrhoea. The bowels were moved six hours before admission.

On admission the right testicle was swollen and tender, there was a large swelling in the right side of the scrotum and the inguinal canal up to the internal abdominal ring. This was dull on percussion and no impulse was felt on coughing. The patient had been vomiting a bile-stained fluid before admission. On May 31st towards the evening sharp pain was felt in the right iliac region and across the abdomen. Vomiting occurred during the day of a copious quantity (about two pints) of bile stained fluid containing what seemed to be intestinal casts of curdled milk enveloped in casein. The patient had not drunk two pints of fluid since admission. On June 1st he suffered most acute pain, and the sickness continued, with similar ejections, the bowels acted and flatus passed. The temperature rose in the evening to 101. The next day the bowels acted again, some pain and sickness being complained of. The temperature in the evening was 99°. On the 3rd the bowels acted again and flatus passed. Temperature 98.2. For the next two or three days there was no action of the bowels and things remained much the same. The swelling in the scrotum and in the inguinal region, which was diagnosed to be fluid, was decreasing. On the 5th the patient vomited twice a large quantity of peculiar pea soup-like fluid after drinking some milk. No action of the bowels had taken place since the 3rd, but flatus was passed daily. During the night of the 6th the patient vomited five times, the vomit being distinctly faecal in character, and when the nurse was out of the ward he walked to the closet, when the bowels were slightly moved. The abdomen was very swollen and the pain very acute.

On the 7th Mr Jalland, in the middle of the day, the patient being under ether, cut down upon the swelling in the inguinal canal, which proved to be, as was expected, an acute hydrocele of the tunica vaginalis, extending almost up to the abdominal ring, and an enlarged testicle, but no bowel was contained in it. At the upper limit, however, the finger could just feel a small piece of bowel, evidently only a portion of the calibre of it, which with very little pressure vanished into the abdomen. This was thought to be the hernia, as nothing else was found. The wound was stitched up and a small drainage tube introduced into the lower end. After the operation the same day, the bowels were moved five times. During the next day the temperature rose to 102.6° and three motions were passed. In three days the temperature became normal, the wound was dressed and found to have united by first intention except at the site of the drainage-tube, which was then removed. During the next seven days the symptoms had all abated, the wound was comfortable, the bowels were moved once by an enema. On June 17th great pain was felt round the umbilicus, and the patient could not straighten his legs on this account, but lay with his knees drawn up. Next day, after an enema, the bowels were moved and the temperature then rose to 101°. He then had diarrhoea for one day, after which the temperature fell and the patient made an uninterrupted recovery only marred by a slight febrile attack on each attempt to increase the diet. He got up on July 12th and left the hospital quite well on July 17th.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY

Resection of Intestine and Immediate Suture in Cases of Gangrenous Hernia

AN ordinary meeting of this Society was held on March 28th, the President, Sir Andrew Clark, in the chair.

Mr KENDAL FRANKS read a paper on Resection of the Intestine and Immediate Suture in cases of Gangrenous Hernia. He related the case of a woman aged thirty who had an umbilical hernia of three months' duration. It became strangulated on Sept 22nd, 1891. Thirty hours and a quarter afterwards herniotomy was performed. The abdomen was found to be full of gelatinous fluid associated with an ovarian tumour. The loop of intestine proved to be gangrenous. Nine inches and a quarter were excised and the ends of the intestine immediately united by means of Gily's suture. The abdominal cavity was closed, and a glass drainage tube inserted, but was removed on the fourth day. The bowels acted regularly after the fifth day and recovery was complete. Five weeks later the abdomen was again opened, and the ovarian multilocular semi solid cyst was removed. The sutured intestine was inspected. The union was perfect, the line of union could be felt as a thickening in the gut, but could not be detected by the eye. Mr Franks discussed (1) the co-existence of ascites with strangulated hernia, and (2) the treatment of gangrenous hernia. The various methods of treatment were reviewed, and the following were some of the conclusions arrived at. Gangrenous hernia might be treated on one of two principles, either by resection and immediate suture or by the formation of an artificial anus. The latter necessitated a secondary operation for its cure, either by the use of Dapuytren's enterotome, or by secondary resection and suture. To estimate the relative merits of these two principles of treatment, the death rate of immediate resection and suture must be compared with the death rate following the formation of an artificial anus, plus the death rate of the secondary operation required for its cure. The death rate in cases of gangrenous hernia treated by the formation of an artificial anus was 80.7 per cent. The death rate of secondary resection and suture for the cure of artificial anus was 38 per cent. The death rate following the use of the enterotome was 7.3 per cent. The mortality which attended resection and immediate suture in gangrenous hernia was shown in a table, presented to the Royal Medical and Chirurgical Society, of 220 published cases to be 48 per cent. Mr Franks concluded that intestinal resection and suture should be the operation of choice in gangrenous hernia, and that simple enterotomy followed by the formation of an artificial anus, should be reserved for absolutely special cases and should be considered as an exceptional procedure.

Mr JONATHAN HUTCHINSON, jun, mentioned a case of a woman aged forty who had had a strangulated hernia for three days. On opening the sac he found the included portion of the gut gangrenous, and there was commencing peritonitis. He then opened the abdomen in the middle line removed altogether twelve centimetres of the intestine, and having taken care to be well away from any damaged portion. The piece removed was shown to the Society and exhibited clearly where the gut had been gripped in the strangulation and some two inches on either side. He had not found clamps of much use and preferred the fingers of an assistant for this purpose. He had used a continuous suture for the mucous membrane and Lembert's suture of fine silk for the rest of the wall in joining the ends of the intestine together. The sac was removed at the first opening and so a radical cure was performed. The patient made an uninterrupted recovery. In this case although no taxis had been attempted, inflammatory changes above the seat of the stricture had set in. The mucous membrane was ulcerated quite through and there was commencing peritonitis. One question in these cases was whether the section through the intestine should be oblique in order to prevent stricture. In his opinion this was not necessary. Another question was whether the resection should be performed at the site of the hernia or through a second opening in the middle line. He was in favour of the

latter plan, as after suture the thickness of the gut was increased, and it might be difficult or even impossible to turn it through a femoral or even through an inguinal ring.

Mr LOCKWOOD said that surgeons up to the present appeared to have been averse to accept resection, their objection being based on statistical grounds. He agreed with Mr FRANKS that resection was an ideal operation. He preferred resecting the intestine through the original wound and cutting through Poupart's ligament if there was any difficulty in replacing the sutured gut. He considered that the method of suture the best with which the surgeon was most familiar.

Mr A. E. BARBER emphasized the importance of removing enough mesentery and intestine to insure having healthy tissues to be are together. He preferred to resect through a median incision, as great freedom for manipulation of the mesentery and intestine was allowed. The plan that he advocated was to remove all the gangrenous parts through the hernial wound and to close temporarily with ligatures the ends of the intestine and then resect them through a median incision. With reference to statistics he suggested that when an artificial anus was made the case was very desperate, entered only being performed in the more favourable cases.

Mr BOWLEY agreed with the position that Mr FRANKS had taken up, though he thought that he had perhaps taken a too favourable view of the operation. From statistics gathered from St. Bartholomew's, Guy's and St. Thomas's Hospitals by Mr BERRY over a period of ten years it appeared that the mortality for all cases of strangulated hernia operated upon was 44 per cent. on 946 cases. The statistics for St. Bartholomew's Hospital, which he had himself collected, showed a mortality of a little over 40 per cent. Mr FRANKS' statistics for resection were almost as good and the explanation of this was probably that unfavourable cases had not all been recorded. It was remarkable how many times some of the surgeons mentioned by Mr FRANKS had performed this operation of resection as out of the enormous number of cases of hernia admitted into St. Bartholomew's Hospital in the last ten years, in only forty two was the intestine gangrenous. It might be inferred, therefore, that resection had occasionally been performed in cases in which the intestine was not gangrenous.

Mr THOMAS SMITH agreed with Mr BOWLEY that the term 'gangrenous' conveyed a different meaning to different operators. The great obstacle to the operation was the depressed condition of so many of the patients which rendered them unsuitable subjects for so prolonged an operation. He did not approve of the use of Senn's plates in these cases. He added that in every case of artificial anus a further operation was not always needed, as occasionally they tended to recover without interference.

Mr CLEMENT LUCAS said that in resection in cases of femoral hernia one question which would have to be settled sooner or later was whether the operation should be completed at the seat of the hernia or through a median incision.

Mr FRANKS in reply stated that he had found the fingers of a capable assistant to be the best form of clamp, that an oblique section was the proper one and that more should be taken from the convexity than from the concavity, and that if the condition of the intestine was doubtful it was better to remove the doubtful part than to risk returning a gangrenous portion into the abdomen. A plan adopted by German surgeons was to fasten the doubtful portion to the abdominal wall and to watch it for twenty-four hours and then to resect or return it according to circumstances. He said that apparently large pieces of intestine could be removed without doing any harm to the patient and without increasing the risk, but that it was very dangerous to leave or suture any unhealthy tissue. In cases of femoral hernia he preferred to open the sac and to clean the parts and then to resect them through a median incision. With regard to sutures, he had always adopted Gile's plan up to the present, but in future intended to use the continuous method. The mortality was probably about 55 per cent. which was much lower than in cases of artificial anus. He referred to a case of colectomy for malignant growth which he had published in the Society's Transactions for 1883 and stated that the patient was at the present time alive and well.

The PRESIDENT observed that the duration of time needed for the operation of resection had not been, he thought, adequately discussed, and that, from a physician's point of view, it was a very important one.

OTHER METROPOLITAN MEDICAL SOCIETIES

HARVEY SOCIETY OF LONDON—A meeting of this Society was held on March 23rd, Mr Malcolm Morris, President, in the chair.—Dr H. A. CALEY read a paper on a case of Simple Ulcerative Colitis: the patient recovering after a long illness. It presented severe constitutional symptoms: those of toxæmia and exhaustion together with local symptoms (tenderness, bleeding diarrhoea) clearly referable to extreme ulceration of the large intestine.—Dr SIDNEY PHILLIPS said that six cases had come under his own observation at the bedside or in the post-mortem room. There might be no melæna throughout though the intestine was deeply ulcerated and perforations had occurred. Perforation might take place with no pain or signs of collapse, and faeces might pass into the peritoneal sac for days before death.—Dr SOLOMON SMITH said that in his experience milk, in consequence of the copious stools to which it gave rise, was far from being a form of diet which gave rest to the colon. It appeared to him that in cases of ulceration hemorrhage was far more likely to be produced by stretching and distension of the intestine by the gases of decomposition than by mere movement.—Dr ALDERSON stated that in cases occurring in children he had found nitric acid with very minute doses of opium useful.—Dr BOXALL remarked that ulcerative colitis was the main feature of mercurialism occurring as the result of sublimated douching in obstetric practice. The symptoms present in most of the cases which had come under his notice were abdominal pain and distension, diarrhoea, tenesmus, with mucus and blood in the stools and little or no fever, but the more generally recognized evidences of mercurialism, such as salivation, loosening of teeth, line on the gums and metallic taste were usually either entirely absent or but slightly pronounced. It was highly essential to bear this in mind and on the first indication of symptoms to stop the use of the mercury to prevent further absorption and to promote speedy elimination. He had been present at the necropsy of two cases in which mercurial douching had been persisted in under the impression that the symptoms betokened septic poisoning. On examination the colon was in each case found to be inflamed and studded with numerous ulcers, especially in the region of the ileo-caecal valve, and in one spot in the more advanced case was actually necrotic and bordering on perforation.—Mr PEYTON BRADLE asked whether any bacteriological examination had been made.—Dr CALEY replied.—Mr TREVES discussed the Pathology of Typhlitis and certain points in its clinical aspect. He pointed out that the majority of cases of typhlitis recover under medical treatment and that only a certain proportion of the cases of relapsing typhlitis call for operation. Before operating in the relapsing form one or other of the following conditions should be present: (1) The attacks are numerous, (2) they are increasing in frequency and severity, (3) the last attack has been alarming, (4) the patient is rendered an invalid, (5) there is evidence of pus about the vermiform process, (6) in every case the enlarged appendix should be capable of being demonstrated during the quiescent period. Mr Treves then described the details of the operation and concluded by giving a description of fourteen cases of removal of the appendix for relapsing typhlitis which had been under his care all of which recovered.—Mr EASTES considered that the cases usually seen by the members of that Society were of a less serious character than those described by Mr Treves but that the treatment required for those milder cases was equally definite and should consist of absolute rest in the recumbent posture, semi-starvation liquid diet alone, and the use of an opiate with some belladonna to prevent constipation.—Mr CRIPPS LAWRENCE mentioned having treated cases: one some six years ago with anti-rheumatic remedies with marked benefit. In an experience of some years, including a fair proportion of cases of typhlitis in various forms he could not recall any that had necessitated operation.—Dr SOLOMON SMITH, Dr SIDNEY PHILLIPS, Dr WILLIAM HILL and Mr HUBERT PHILLIPS also took part in the discussion.—Mr TREVES replied.

ISLINGTON MEDICAL SOCIETY—At the last meeting of this Society Dr ALEXANDER MORISON read a paper on the Causes and Treatment of Dilatation of the Heart, in which he con-

sidered (1) the relation of the nervous system to the condition under consideration, (2) the conditions of the heart itself as to (a) its mechanical efficiency, (β) its nutrition, (γ) its contents—the quality and quantity of the blood, (3) the influence of the extra cardiac vascular system—systemic, arterial, venous and pulmonary, (4) the influence of diaphragmatic and general muscular activity and the retardation of these important functions by obesity, (5) the influence of extra corporeal conditions and agents—namely (a) atmospheric pressure, its diminution and increase, and also the effect of variations in temperature, (β) the influence of accidents, including shock, (γ) the effect of improper quantity in food and drink, (δ) the influence of drugs. From the limited time at his disposal Dr Morison naturally dealt cursorily with several of these topics, but emphasised the importance of the nervous factor in these cases and discussed at length the importance of the coronary blood having a maximum oxygenation. He considered heart-failure from nerve influence to be at least of two kinds—namely, (1) vagus inhibition from gastro intestinal contraction or emotional shock, and (2) exhaustion of the cardiac reflex centre from sustained over action of the heart due to disease or undue exertion. Amongst other points of treatment he discussed the views of Dr Oertel of Munich.

MIDLAND MEDICAL SOCIETY

MEETINGS of this Society were held on Feb 8th and 22nd at the Medical Institute, Birmingham, Mr Eyles, President, being in the chair.—Mr WOOD WHITE showed a woman aged thirty with a Sarcoma growing from the periosteum of the inner wall of the orbit and the side of the nose. Two months before her admission to the Eye Hospital a discharge was noticed from the nose on the same side, and examination showed that the upper part of the organ was occupied by a soft spongy and vascular growth.—Dr PURSLOW showed a Multilocular Ovarian Cyst which he had removed by abdominal section from a woman aged forty six at the Queen's Hospital. The tumour had been noticed for four months and at the time of operation was about the size of the uterus at term. A median incision three inches long was made, the larger cyst was evacuated by the trocar, and several smaller cysts were broken up by the trocar and finger and the mass withdrawn from the abdomen. The fluid measured 169 oz., and the remaining part of the tumour weighed 31 oz. No flushing or drainage tube was used, and the patient made an excellent recovery.—Dr MALINS showed (1) a large Hæmatosalpinx and (2) a Dermoid Cyst of the Ovary. He also exhibited a Myeloid Sarcoma of the Humerus with spontaneous fractures from the arm of a boy aged ten years. Two years ago he fell and fractured his humerus, the year following he fell and fractured it again, and six months ago he again fell and injured his arm. Since the first injury he had always noticed a lump in his arm, but it did not increase in size until after the last one. This specimen raised the question as to whether the sarcoma was the result of the various injuries, or whether the fractures were secondary to the new growth.—Mr HASLAM read a paper on the Value of the Ligation of the Lingual Arteries in Malignant Disease of the Tongue.—Mr THOMAS exhibited a boy, aged twelve, who had an Ununited Fracture of the Right Clavicle. When about a year and a half old his clavicle was fractured by an accident, but he was treated at one of the hospitals, non union seemed to have resulted. The following was the present condition. The right clavicle had been fractured a little externally to the centre. The fractured ends could be readily separated and moved, but in a state of rest the outer fragment lay below and in contact with the inner for nearly an inch, there was well marked fibrous union between the fractured ends. The shaft of the clavicle was atrophied, but the muscles of the shoulder, and especially the deltoid, were much hypertrophied. Any kind of movement of the upper extremity could be performed with ease and quickness. As such complete use of the arm was acquired Mr Thomas had given up the idea of any further operative proceedings.—Mr MARSH showed a youth aged twenty, the Right Lobe of whose Thyroid Gland, with the central part, he had excised three weeks before for acute bronchocela, causing dyspnoea. The enlargement of the neck had only been noticed four months prior to admission into hospital on Feb 2nd. There were no cardiac symptoms or exophthalmos, but the veins on the

A median incision was employed and the patient made a rapid recovery.—Mr WOOD WHITE showed for Dr SUCKLING a woman aged forty two, suffering from Paraplegia supervening upon Exophthalmic Goitre. Dr Suckling considered that descending sclerosis of the motor tracts had followed upon a lesion in the region of the floor of the aqueduct of Sylvius.—Mr WOOD WHITE showed a boy aged six with a firm, elastic and fairly movable tumour growing from the upper part of his right orbit and bulging the upper eyelid. The growth was first noticed six months previously, and, three months before admission to the Eye Hospital, was removed at another institution. It recurred very rapidly, and Mr White had no doubt that the tumour was a sarcoma, he contemplated its removal at once, sparing if possible the eyeball.—Dr SHORT showed a man aged sixty two who during the last eighteen months had passed two large Gall stones weighing respectively 309 grs and 214 grs, at an interval of eight months. A review of the symptoms made it most probable that the stones had ulcerated from the gall bladder into the hepatic flexure of the colon. The first calculus was perfectly smooth and the second was faceted at each end.

Reviews and Notices of Books.

Text book of the Embryology of Man and Mammals. By Dr OSCAR HERTWIG, Professor Extraordinarius of Anatomy and Comparative Anatomy, Director of the Second Anatomical Institute of the University of Berlin. Translated from the Third German Edition by EDWARD L. MARK, Ph.D., Hersey Professor of Anatomy in Harvard University. Pp 670, with 339 Figures in the Text and 2 Lithographic Plates. London: Swan Sonnenschein and Co 1892.

DR. MARK has done good service to the student in translating this valuable treatise into English. Although in Balfour's great work, in Foster's Embryology and in Haddon's work the main facts in development are placed within the reach of the morphologist and the physiologist, room still remained for such a *résumé* of the whole subject as that before us. Balfour's treatise is now twelve years old, and much has been done in the way of observation and many improvements in the means of staining have been effected in the interval. Foster's excellent little manual is chiefly concerned with the fowl. Haddon's text-book is short, and also restricted in its scope. Hertwig is himself known as an original worker, and the reader will find in these pages a fairly full and satisfactory account of all that has been done in this department of science up to the spring of 1890. The translator must have worked hard to have completed his translation in the course of a year and a half, especially as the rendering of the German is all that could be desired in clearness and accuracy.

The work is divided into two parts, the first of which deals with the early stages of development of the ovum, whilst the second part is occupied with the development of the organs. The earliest changes that take place in the unfecundated egg or those accompanying maturation of the ovum, is the translation of the germinative vesicle from the centre to the surface, the shrivelling of the vesicle coincidentally with the escape of fluid from its interior, the disappearance of its nuclear membrane and the breaking up of the germinative clot, and finally the formation of the nuclear spindle and the extrusion of the polar cells or direction globules, are all carefully given. The author was himself the first to point out that a distinction must be drawn between the nucleus of the immature mature and the fertilised egg, or in his nomenclature between the germinative vesicle, the egg nucleus and the cleavage nucleus. He remarks that, although the researches on the phenomena of maturation still present numerous gaps, it may, nevertheless, be held "that eggs with a germinative vesicle are

never capable of fertilisation, that the germinative vesicle is without exception dissolved, and that there is formed out of its components a very small egg nucleus." During the change polar cells are extruded. In regard to the polar cells no satisfactory explanation has been advanced but he notes the discovery by Weismann and Blochmann that in eggs which are developed parthenogenetically only a single polar cell arises. By some these cells have been considered to be male constituents of the original hermaphroditic egg which are thrown out to be subsequently replaced by fertilising germinal elements of the male. Hertwig himself however inclines to the opinion that the ovum was originally capable of dividing into many cells or eggs and that the polar cells are really abortive eggs.

A very interesting section is devoted to the history of the vertebral theory of the skull. The attempt to solve the problem of the composition of the skull was made by Owen and Goette, the former of whom recognised three vertebrae in this part of the skeleton which he named respectively the ear, eye, and jaw vertebra, and he and Goethe pointed out the general similarity that exists between a vertebra and the occipital bone whilst an effort was made to show a similar analogy between a vertebra on the one hand and the posterior body of the sphenoid, with its greater wing, and the parietal bone on the other the third cranial vertebra being represented by the anterior portion of the body of the sphenoid and the lesser wings of the sphenoid and the frontal bone. Even a fourth cranial vertebra was recognised in the ethmoid bone. In this form as Hertwig observes which underwent numerous modifications in details, the Owen Goethe vertebral theory of the cranium dominated morphology for decades and formed the foundation of many investigations. "It had a stimulating and fruitful effect until with a deeper insight into the structure of vertebrates it was abandoned as defective and erroneous giving way before the force of numerous newly discovered facts." Owen, who devoted so many months or years to this subject, is not even mentioned. Huxley first ventured to attack the view which threatened to become an accepted one, on embryological grounds maintaining that no single cranial bone can be recognised as a modification of a vertebra, that the skull is no more a modified vertebral column than the vertebral column is a modified skull, that, rather, both are essentially distinct and different modifications of one and the same structure. Gegenbaur next taking up the subject where Huxley had left it, produced evidence, also derived from embryological research, that the primordial cranium has arisen by fusion from a number of segments these segments being equivalent to but not modifications of vertebrae. He dwells upon the arrangement of the chief nerve trunks and holds that there are in the cranium nine pairs of segments which early fuse together, but whose original separation is still indicated by the passage through them of the nine segmentally arranged cranial nerves. Hertwig then proceeds to give his own views on the points in dispute.

The long discussion in regard to the origin of the *ossicula auditus* seems to be in a fair way of settlement, the incus and malleus being segments of the proximal portion of the rod which is familiar to all as Meckel's cartilage, whilst the stapes appears to have a double origin, the plate which fits into the fenestra ovalis being differentiated, as Parker maintained, from the cartilaginous capsule of the labyrinth, and therefore corresponding with the operculum of the amphibia, whilst the arches proceed from the upper end of the second visceral or hyoid arch which lies in contact with the capsule of the labyrinth, the ring like form being due to the circumstance that the tissue from which it is formed is traversed by a small branch of the carotis interna, named the arteria mandibularis or perforans stapedia. The malleus and incus therefore belong to the first visceral arch and the

stapes to the second, and this view is supported as Huxley has pointed out, and as is admitted by Hertwig, by the fact that the muscle of the stapes is supplied from the nerve of the second visceral arch the nervus facialis, whilst the muscle of the malleus receives a branch of the trigeminal which is the nerve of the mandibular arch.

The difficult and obscure subject of the development of the bloodvessels and of the blood on which the last word has been by no means said is well handled, and the conflicting views of Kölliker and his adherents that they arise from the mesoblast and of Rücker, Strann and, it might have been added of Cornu that they are primarily derived from the cells of the hypoblast are clearly given on the whole. The author does not consider the question of the source of the cell layer in which in the region of the opaque area, the formation of blood takes place as ready for final judgment, but as regards the further changes by means of which the cell layer under consideration is converted into connective tissue and blood he adheres to Kölliker's views. To several of the chapters a historical appendix is added which is in every instance valuable, giving an admirable account of the mode in which the views at present held have been evolved from the loose statements of the older observers and writers. In conclusion the work may be taken throughout as an authoritative exposition of the present state of our knowledge of embryology.

Bibliothèque Photographique de l'Hôpital de la Salpêtrière. Application des Sciences Médicales et Physiologiques. Par ALBERT LONDE. Paris Gauthier Villars et Fils. 1893.

Most of those who have followed M. Charcot's publications are by this time well acquainted with the admirable photographic representations he introduces in order that he may add to the value of his descriptions and have also recognised that these photographs can only be the result of most careful study and of the application of an almost perfect technique. We have now in our hands a most admirable manual on medical photography by M. Londe, Directeur du Service Photographique à l'Hôpital de la Salpêtrière in which are combined both descriptions of methods and of apparatus and very fine examples of the art that he describes. The work is very complete not only in the fact that it gives all this information but also in that it indicates very clearly to what extent photography may be called in to assist in making permanent records of medical observations—in the term "medical" must also be included 'physiological' records for of the examples and plates given some of the most admirable are those made to record physiological experiments. To indicate the lines on which the author proceeds we may merely give an example. All who have worked at photography of special limbs and feature know how difficult it is to ensure the hand for instance, keeps perfectly still whilst a photograph is being taken, in some cases it is impossible, in others it may be managed comparatively easily. In the former instances M. Londe simply takes photographs first instantaneously and then gradually increasing the length of exposure, knowing the exact exposure in every instance. He is thus able to determine at what rate movements are taking place, through what range these movements go on, and by the distinctness of the different images of the moving hand to determine which movements occur most frequently. Where it is possible to keep the hand at rest this is done by placing the thumbs together where the back of the hand is to be reproduced, and the little fingers together where the palm has to be reproduced, resting them on a kind of sloping desk in front of the patient. In this way the most minute details may be brought out very distinctly, the photographs serving in some instances the purpose even of a delicate cast. A few other examples may be mentioned—viz., plates illustrating deviation of the vertebral column in the case of

syngomyelia, the positions and movements of patients suffering from paralysis agitans, the position of the head in cases of hysteria, appearances of the features in acromegaly and paralysis agitans, the appearance of the feet in acromegaly and in cases of epilepsy, the rhythmical movements seen in chorea, a series of photographs of the effects produced by faradaic currents on certain of the facial muscles, the phases through which an epileptic passes, the photograph of epileptic walks and of rapid movements, specimens of reproduction of writing, anatomical photographs such as those of the brain and of sections of the spinal cord, of various forms of cultures, of the hands of different artisans, showing the special features by which these are characterised, and of other medico-legal subjects. The photographing of microscopic specimens and of test tube cultures is also mentioned, whilst the treatment of negatives, the preparation of positives for lantern work, the preparation of mechanical prints, of gelatine printing plates and the like, complete the work, which is one that should be in every hospital and in the library of every laboratory.

Mineral Springs and Health Resorts of California By WINSLOW ANDERSON M.D., M.R.C.P. Lond. M.R.C.S. Eng., Joint Editor of the *Pacific Medical Journal* San Francisco The Bancroft Company 1892.

THIS work is a prize essay which obtained the annual prize of the Medical Society of the State of California for the year 1889. The writer has personally visited the prominent mineral springs and health resorts of California and has satisfied himself that this State possesses "as valuable mineral springs as any to be found in the world" and "that all that is needed to make them as serviceable in the restoration and maintenance of health as their famous sister springs in the East and in Europe is their further development, their chemical analysis and the scientific administration and application of their waters." The author, after obtaining analyses of every European and American spring of any note, has applied himself to the task of analysing the Californian waters and comparing the results. He is of opinion that "the Californian waters compare favourably with those of the European and Eastern States, in fact, many of them are almost identical in composition." The work contains the names of over two hundred Californian springs, with about one hundred analyses, besides two hundred analyses of all the famous springs in America and abroad. Short sketches are introduced on the fertility and natural productions of California, its history, climate rainfall &c., and there are also comparative thermometrical tables. The work is profusely illustrated, the illustrations being fairly well executed, but for the most part such as we are accustomed to more in a book of travels than in a scientific work. Writers on climate, meteorology, balneo therapy, &c., and kindred questions are beset with the difficulty that no materials for scientific precision with regard to these important subjects hardly exist and the temptations to flowery description and "tall talk" are very strong. Dr Anderson makes laudable efforts to collect as many scientific data as possible, and his tables of analyses of Californian springs are much the most complete with which we are acquainted, but he repeatedly wanders off into enthusiastic panegyrics upon "the golden west," "the balmy luxuriance" of the climate &c., and he studs his pages with poetical extracts, often of rather hazy eloquence.

The most striking feature of the Californian springs is their variety. Amongst the hundred springs of which the author supplies analyses examples are found of all the chief varieties of spa. Alkaline and alkali carbonated springs are numerous. One of these—Etna Springs—has a composition closely resembling that of the Ems waters, both containing chloride and carbonate of sodium and carbonate of magnesium and

calcium. Light carbonated waters, either simply mildly alkaline or containing small quantities of iron or sulphur, are found at Agua de Vida, Allen Springs and elsewhere. Stronger ferruginous and sulphurous springs abound. At Anderson Springs in Lake County are found mild alkali-sulphuretted waters, mild chalybeate waters, springs containing free sulphuric acid, light saline sulphurous waters, a magnesium spring rich in Epsom salts and a hot sulphurous spring used for bathing. This variety of waters in a single locality is typical of the wealth of California in mineral springs. Borax springs are amongst those most characteristic of the country. They are found in various parts of the State. The author informs us that during the last twenty years California has produced \$5 000 000 worth of borax. Moor or mud baths in association with hot saline and sulphur waters are found at Byron Springs in Contra Costa County, about sixty-eight miles north east of San Francisco. This seems to be one of the most notable of the Californian spas, containing more than fifty springs, some hot, others cold, carbonated, saline, sulphurous, chlorinated &c. We have not space to follow the author through his description of these and other springs.

There can be little doubt that a great future lies before California as a sanatorium. It possesses three grand requisites for such a purpose—viz., a very fine climate, great natural beauty, and great wealth of mineral waters. Of the climate much has been written, and, in spite of the occasional extravagances of enthusiastic writers, we may fairly admit that its merits entitle it to rank amongst the best climates in the world. The most favoured part is probably that constituting the littoral and adjoining regions from Monterey to San Diego. Whilst admitting that the enthusiasm of writers on California has very solid foundations in fact, we would counsel such writers to give us a little less eloquence and a little more of accurate and well sifted scientific data.

Ueber Echinokokkus der Pleura und die ihn vortäuschenden Localisationen der Echinokokkenkrankheit Von Professor Dr. CARL MAYDL. Wien. Verlag von Josef Sáfár 1891.

DR CARL MAYDL, in his monograph on echinococcus of the pleura gives a fairly complete account of this comparatively rare disease. He supplies workers with abstracts of statistics and pathological records collected by various observers who have come across cases, and from his remarks on these we gather that he considers the prognosis exceedingly bad unless operation be resorted to. He gives very good tables for diagnosing solid from cystic tumours and intra-thoracic echinococci from pleuritic exudations. He points out that in the former case the pain is longer continued and that it is not so strictly localised, that the dyspnoea is much more marked and leads to far graver results, that the expansion of the thorax is more irregular and also more circumscribed, that the dullness of percussion is localised and that it is not specially marked at the lower and posterior part of the chest, also that there is no well defined "water line" of such dullness, that it may extend to the opposite side of the chest without filling up the whole of one side, that the respiratory murmurs are completely lost, that bronchophony and egophony are absent, that there is little fever, but that in the later stages of the disease there is great cachexia, anæmia and emaciation.

As regards the treatment, the author evidently believes in puncture with or without the injection of iodine, though he seems to prefer simple operation with the use of antiseptics. He points out that it is of course, often necessary to incise and even to remove some of the ribs in order to obtain the best results. In fact, he seems to think that the more radical the treatment (taking the nature and the extent of the disease into account), the better will it be for the patient.

LIBRARY TABLE

The Veterinary Journal London Baillière, Tindall and Cox.—The March issue of this journal contains a number of interesting papers, amongst which we may note an article by Professor De Jong on Sarcptic Scabies in the Fox, the first time this disease has been described in this animal in England, another on the Castration of a Cryptorchid Horse the operation being rendered more difficult by the presence of a serous cyst in the testicle, but the obstacle was successfully surmounted by Professor Degive, who is the director of the Brussels Veterinary School. There is also a valuable contribution to the subject of protective inoculation for swine plague from the pen of Professor Barker of the Patho Biological Laboratory of the Nebraska State University. Mr Pike of Cleveland, Ohio, describes a new malady of cattle, known in the States as the "corn stalk disease," which appears to be due to eating maize stalks late in the autumn. The cause of the disorder, which is of a rather serious character, is reported to be a vegetable parasite—a belted germ which is neither a coccus nor a bacillus though much resembling these in form. Mr Moore gives a case of tuberculosis in the dog complicated with ascite, and Professor Leclanche, of the Toulouse Veterinary School, continues his essay on Influenza in the Horse. Altogether the number of this periodical is an excellent one and contains much that is instructive to the pathologist.

Lehrbuch der Specieellen Chirurgie für Aerzte und Studierende Von Dr. FRANZ KOENIG, Ordentlicher Professor der Chirurgie, Geheimer Medicinal Rath, Director der Chirurgischen Klinik in Goettingen. Sechste Auflage. Band I. Berlin August Hirschwald. 1893.—This text book of regional surgery is too well known to need any but a brief notice from us. The author has made a careful revision of this, the sixth, edition. The second volume is in the press but it was thought better to issue the first at once and not to keep it back for its fellow, as originally intended. This volume includes the sections devoted to the injuries and diseases of the head, face and neck. The text is illustrated with 139 wood engravings.

Analytical Records

FROM

THE LANCET LABORATORY

NON IRRITATING NURSERY POWDER.

(C. H. GRIFFITHS OPENSHAW.)

THE composition of this powder according to our examination is simple. It is perfectly free from irritants is entirely soluble in hot water and contains a well known and mild antiseptic. The preparation is made attractive by the delicate and fragrant odour of rose extract.

ESSENCE OF BEEF AND CONCENTRATED BEEF TEA.

(BRUCE & CO, LIMITED ST GEORGE'S HALL, WALHAM-GREEN S.W.)

Portable and concentrated forms of food are useful and valuable in their way, but they cannot be regarded as being always fitted to replace the freshly prepared products. Whilst a desirable degree of concentration of the nutritious and stimulating elements is effected flavour is often sacrificed, and the process may not improbably affect the digestibility of the constituents. We have examined from time to time a great number of concentrated foods, notably beef extract and essences which, similar to the above are more or less satisfactory as regards flavour and degree of concentration, but, whilst many of them contain in large proportion the stimulating principles of the meat from which they are obtained, certain of them are found to be nearly if not quite destitute of the really sustaining and nutritious elements fibrin and albumen. This does not apply,

according to our examination, to the concentrated beef tea of the above firm, although we cannot agree that fibrin and albumen, and especially the former, were present in large proportion. This preparation would certainly be improved and be all the more valuable as a food if it contained more of this substance. In regard to the merely stimulating constituents of beef, however, it is highly satisfactory. Thus it contains 63.87 per cent. beef extractives, no less than 10.96 parts of which are nitrogen, whilst the mineral matter, rich in soluble phosphate, containing also common salt, amounted to 6.02 per cent. It yields a pleasantly tasting and agreeably saline liquor when dissolved in warm water. The essence is a clear amber coloured jelly which, on analysis, was found to have the following composition: Moisture, 90.23 per cent. extractives, 8.79 per cent., containing 1.65 parts nitrogen mineral matter 0.98 per cent., consisting almost wholly of soluble phosphate. It contains, therefore, the soluble constituents certain % of beef. The taste of its solution is somewhat insipid unless salt is added. Both preparations it is satisfactory to add, are free from injurious preservatives.

HARVESTS LENTIL FOOD

(W & D HARVEST LONDON F.C.)

The high amount of nitrogenous matter in the lentil has brought this pulse food into favour, but the taste of the lentil does not appeal to all palates, and hence many excellent preparations are made, of which the above is a type in which the flavour of the ground lentil is improved and made attractive by incorporating with it other ingredients without detracting from its food value. The taste of the above preparation is good, though somewhat saline. It is well suited for the preparation of soups, porridges and other forms of food. Lentil was the only form of starch that was recognised under the microscope.

DR LANGEN'S SUGAR OF MILK

(BURROUGHS BROS 66 BASINGHALL STREET, E.C.)

It is an accurate statement, we find, that this preparation is chemically pure. It dissolves completely in hot water and yields absolutely no mineral matter on incineration. Analysis gave figures which approximated to 100 per cent. real lactose, calculated on the dry product. Its uses are manifest. We must again protest against the name of a medical practitioner being made use of in the title of this or any other preparation.

PUREST ETHYLIC ETHER.

(SALMON & CO, LIMITED RAINFHAM ESSEX.)

We have carefully submitted this product to analysis, and in every respect the results obtained were satisfactory. If boiling point and specific gravity are indicative of purity, then it is irreproachable in character for the former was found to be 35°C and the latter 0.721, figures coinciding exactly with chemically pure ether. Moreover, it gave absolutely no residue on evaporation, was entirely free from acid and contained no products of oxidation or decomposition. It would be well if all preparations used in medicine were equally pure.

GENUINE OLD COGNAC

(MESSRS GAUTIER FRÈRES AND HENRI TURPIN, THIRSK, YORKSHIRE)

Chemical analysis cannot fully establish the actual origin of a spirit, but doubtless this is a genuine cognac. It is shipped from the well known house of Messrs Gautier Frères, Cognac, and each bottle bears the stamp of the "Union des Fabricants." We have submitted it to analysis, with the view of determining how far the results coincide with genuine brandy. As will be seen from the following result, they coincide in every detail. Thus the extract amounted to 1.17 per cent., the mineral matter to 0.07 per cent., the alcohol, by weight to 40.45 per cent., by volume to 47.83 per cent., equal to 83.83 per cent. proof spirit. The extractives on incineration evolved a smell which was very characteristic of genuine cognac. Rough as it may

appear, this is a test which in experienced hands affords fair evidence of the origin of the spirit. As regards alcoholic strength it is somewhat low, but the taste is peculiarly smooth and satisfactory. Much has been said about spurious brandy of late, but we have reason to believe that this is a genuine article.

VINCERDA COCA WINE

(PHILIP CERDA, 30, LEICESTER PLACE, LEICESTER SQUARE, W.C.)

The valuable therapeutic principles of the leaf of erythroxylon coca are evidently contained in this agreeable wine as on suitable treatment cocaine was successfully extracted and identified. Extended analysis gave the following results. Alcohol by weight 13.00 per cent, by volume 16.05 per cent, equal to proof spirit 28.13 per cent., extractives, 4.99 per cent., mineral matter, 0.21 per cent. In respect of spirit strength, therefore, it is similar to good port, possesses a similar flavour but is less sweet and not so full bodied. The valuable coca leaf extractives, in fact, replace to an extent the less valuable sugar of ordinary wine and they communicate an unmistakable flavour to the wine, affording some evidence of the genuineness of the preparation. The value of coca wine as a restorative and stimulant is now recognised, and where indicated the above preparation may be suitably prescribed.

EUCALYPTUS GLOBULUS OIL (PEATYPUS BRAND)

(THE TASMANIAN EUCALYPTUS OIL COMPANY 138 LEADENHALL STREET E.C.)

This preparation was marked, as all similar preparations containing a desirable proportion of eucalyptol are marked, by an especial fragrance of smell. Submitted to fractionation the following results were obtained. At 170° C 6 per cent distilled over between 170° and 172° 28 per cent, between 172° and 175° 18 per cent, between 175° and 177° 19 per cent, between 177° and 178° 3 per cent, between 178° and 180° 11 per cent, and the remaining 15 per cent. came over at points above 180° C. There were traces of water in the oil. Inasmuch as the boiling point of eucalyptol, which is regarded as the valuable active principle of eucalyptus oil, is about 176° C, it will be seen that this brand (the Peatypus) is desirably rich in this most important constituent. The specific gravity of the oil at 155° C was found to be 0.9172. Further examination elicited the admirable purity of the product. Eucalyptus is an excellent, agreeable and effectual antiseptic, and in view of the foregoing results the suitability of this specimen for all purposes where antiseptic treatment is required cannot be disputed.

SODA WATER IN SYPHONS AND A DEVICE TO SECURE ITS GREATER ORGANIC PURITY

(THE BANGOR CITY MINERAL WATER COMPANY, BANGOR, WALES)

We have on a previous occasion examined the soda water made by this company, but it is only just to recognise the efforts which they have quite recently made to still further improve the quality of the aerated waters distributed in syphons. Syphons, being carefully filled, will frequently show a considerable amount of dirt or the water will exhibit a more or less opalescent appearance. This may be due to an accumulation of dust, meal or other objectionable matter in the nozzle of the syphon whilst it has been lying empty. By means of a syphon cleansing jet which this company have invented, a specimen of which we have examined, the interior of the syphon nozzle is thoroughly cleansed before it is attached to the filling machine. The jet, if it is to be used for cleaning the nozzle only is attached to the ordinary water supply, but if required also for the rinsing out of the syphon it is attached to the pressure cylinder containing carbonic acid gas. The action is entirely automatic, and twenty dozen syphons, it is stated, may be easily cleansed by means of this device in an hour. We regard this as an important advance in the manufacture of pure aerated water, as we have frequently had occasion to complain of the dirty state of soda water and its consequent organic impurity, doubtless due, not to the water as it flows from the filling apparatus, but to the accumulation of dirt in the nozzle of the syphon. It is scarcely necessary to add

that the soda water obtained from syphons so treated was found on examination to be perfectly free from organic matter. Thus the residue, on evaporation, did not show any perceptible discolouration or clearing on ignition, a test which is not responded to satisfactorily by some of the soda water commonly met with. Each syphon (one pint and a half) submitted to us by this company was found to contain 10.5 grains of bicarbonate of soda.

New Invention.

APPARATUS FOR FRACTURES OF THE LOWER JAW

The general surgeon, when called upon to treat a case of fracture of the lower jaw, commonly finds that, should a splint be necessary, he has to set aside the ordinary surgical rules for the treatment of fractures elsewhere, because of the special conditions by which this class is attended. In fractures of other bones a splint or the material for the making of one is usually at hand and can readily be applied. The common method of treating fractures of the jaw with four tailed bandage and gutta-percha may fairly be considered unsatisfactory. To provide an effective and permanent splint for the jaw the general surgeon has often to call upon a dental surgeon for a special apparatus, and thus much valuable time may be lost before the fracture can be set. I am convinced that it is to this delay that most of the troubles incidental to this kind of fracture owe their origin. The saliva, laden with decomposing discharges and debris of food &c bathes the ends of the bones and the soft tissues surrounding them. This condition is made worse by the constant play of the ends, due to the uncontrolled action of the masticatory muscles and to gravity, leading to abscess, necrosis of the ends and diffuse inflammation of the surrounding soft tissues.

I wish to draw attention to a new form of apparatus which I have devised for fractures of the horizontal portion of the jaw. The following are the chief advantages which may be claimed for it. 1 It can be applied in a few minutes owing to its being universally adaptable. 2 It can be applied over and over again in different cases without alteration or renewal. 3 Its parts, being of plated metal, are easily kept clean. Bandages need not be used with it. It allows of free application of cleansing washes within the mouth. 4 Its application involves no other parts but the lower jaw. It interferes but little with eating and drinking or speaking and sleeping, because of the swivel action of its clamps. The splint consists of a plated metal horseshoe shaped piece, which rests upon the table, and a similar one which is applied below the chin. These are fastened together by two movable clamps. To apply the splint, the mouth plate or metal gutter which is to take the teeth, or jaw if there be no teeth, is lined with ordinary splint gutta-percha. This is then warmed and driven down on the teeth and gums as far as the shallow plate allows. The chin plate, lined with the two layers of wash leather, is put into position and held there. The swivel clamps are then fitted into both plates and, by the thumbscrew to each, can be made to clamp the plates together until the requisite tension is attained. The splint is made by Messrs Arnold & Smith Ltd.

March 22nd 1893

ROBERT C ACKLAND

THE LANCET.

LONDON SATURDAY, APRIL 8, 1893

WE present our readers to-day with the results of an inquiry which in very special circumstances we have instituted into the water supply and drainage systems of the city of Chicago. If we had undertaken the examination of such matters in connexion with any town in the United Kingdom the proceeding would have demanded no apology. If we had prosecuted our inquiries in any plague stricken district abroad there would have been ample precedent, but the present is, it must be confessed, beyond the scope of any similar journalistic enterprise that we are able to quote, and must therefore be justified upon its merits if it is to be justified at all. The reasons that have moved us are very simple and can be stated in a few words. They will, we hope, be found to be cogent enough to prevent any misunderstanding of our motives and even any serious complaint as to the course that we have pursued.

It is perfectly well known both here and in America that the condition of the Chicago River and the state of the Chicago water supply have been matter of much adverse criticism for some years past, and have given occasion not only for discussion to critics but also from time to time for anxiety to the city authorities. A member of our staff, travelling last autumn in the United States, visited Chicago, and heard both there and elsewhere much discussion and no little censure of the sanitation of the city. Struck with the gravity of the situation which would arise if the thousands of visitors to the World's Fair should find themselves restricted to an unwholesome water supply, in a year which is only too likely to witness a recrudescence of the cholera outbreak of 1892, he prosecuted such inquiries as a brief opportunity enabled him to make upon the spot, and took advantage of a private introduction to secure the services of an agent resident in the city who could follow up his inquiries if it were desired to pursue the inquiry further after his own return to this country. He was thus, when he arrived at home, in a position to report to us not only the current rumour as to the dangers lurking in the Chicago River and Lake Michigan, but also to give from authoritative sources an outline sketch of the systems of drainage and water supply which are in fuller detail laid before our readers to-day, and thus to show that the talk of the streets had at least that colour of probability which is afforded by indisputable theoretical shortcomings in the design of the city sewers and the city water works. There was thus presented to us as the Editors of THE LANCET a duty which we were bound to undertake. So long as the sanitation of Chicago was a matter of purely domestic concern to the Chicago people, it was beyond our province, but when it had plainly become a matter of possibly life and death significance to thousands of our fellow countrymen, who are proposing to accept the invitation of the American people and visit Chicago during the present year, we felt that the time had arrived, not for searching out precedents, but for making a new departure

and setting at rest the disquieting questions that had been so pressingly forced upon our notice. We accordingly commissioned the gentleman who had made the preliminary inquiries to complete the task which he had undertaken, and charged him to spare neither trouble nor expense to make the inquiry thorough and to obtain such information as would enable us and our chemical advisers to submit to our readers a complete and trustworthy account of the matters brought into question and such advice as the circumstances of the case might demand.

So much it has seemed necessary to say upon the threshold of the present discussion, not only in our own justification but also by way of explaining and defining the limits which we have imposed upon ourselves in dealing with the questions raised. The matters treated of are matters of capital importance to the people of Chicago, and there is much which, if we were free to treat of them under that point of view, it would be fitting and even necessary to say but which has in the existing circumstances been left unsaid. Our object has been the practical one of ascertaining as far as possible what risks, if any, are involved in the visit of our fellow countrymen to Chicago and of contributing to the success of the Exhibition by such counsels as may enable visitors and their entertainers alike to be upon their guard against such dangers as may be avoided or minimised by vigilance and well directed observance of the laws of health. It will be found upon reference to the report of our Commissioners that there are some points, and especially the unscientific use of ice in cooling water, to which the attention of the public in Chicago needs to be most carefully and seriously directed. These will, we hope, receive the consideration to which they are entitled on the part of all concerned. But it is also pleasant and not at all surprising to find that defects have been magnified and faults exaggerated by ill informed rumour, and that it may reasonably be hoped that the great enterprise of the International Exhibition will be carried through without any such untoward concomitant as an outbreak of epidemic disease. That it may be so is the sincere wish of all parties on both sides of the Atlantic. We are the better able to express the sentiment because we can indulge the hope that our well intended criticisms may not be without some effect in helping to secure this great result.

THE experiment in "the life of a free puncture," initiated many years ago by Leicester is being put to the test. The particular freedom in question is the freedom by which suffer from small pox. The experiment is interesting to the public, but it is not so highly so as some of the sanitary advisers are apt to think, save to the people of Leicester themselves. Still it has a certain human interest, and deserves to be watched with attention by all intelligent students of human nature, and especially by students of human folly. Two contributions to the study of great value have appeared lately in our columns: one, a letter from Dr PRIESTLEY,¹ the medical officer of health for Leicester itself, the other² a paper entitled "A Critical Examination of the so-called 'Leicester System' of Isolation and Quarantine," by Mr A. T. BREMNER, L.R.C.P. Edin., member of the Leicester Fever Hospital Com-

¹ THE LANCET March 18th, 1893.

² THE LANCET March 25th, 1893.

mttee Two gentlemen more entitled to speak with authority and information on the subject could scarcely be found, and we are glad to have been the medium of conveying the important information they have to give and the light they have to throw on the "marvellous success which for the past twenty years has attended the efforts of the sanitary authorities in stamping out small pox without recourse to vaccination." These words were used by a member of the Leicester Town Council as lately as November last, and they are open to the criticism of being at least incomplete and hardly candid. The writer was in the position then to know, what we long since pointed out, that so far as the protection of Leicester was concerned it depended chiefly, as the protection of every town must do, on vaccination. As far back as June, 1886, we ascertained by careful investigation on the spot that whenever a case of small pox occurred and was notified in Leicester, it was taken charge of by revaccinated persons and that all the persons exposed to its influence in the house in which it occurred were not only isolated but were revaccinated. This has been the system of the medical officers of health of Leicester before and since then, and yet up to November last the members of the Sanitary Committee and others have not hesitated to represent that they protected Leicester "without recourse to vaccination." For years past this delusion has had a certain plausibility and acceptance throughout the country. Vaccination has been ignored in the Leicester reports and sanitation has been all in all. Not in Leicester only, but in the country generally, small pox has been in abeyance. In London and in the twenty eight large towns the record has been—no death from small pox and scarcely even a case of the disease. It was easy in such circumstances to protect Leicester or any other place with a cordon of vaccinated persons to deal with the stray cases that occurred and were immediately notified. Everyone that knew the nature of small pox epidemics foresaw that, though this "system" might have a show of success whilst the disease was in abeyance, it would break down as soon as it began to reassert itself, and, as in "the life of a free people," they began to object to isolation as well as to "quarantine." "Quarantine," says Mr BREMNER,³ "being a voluntary act, part of the life of a free people, we met in October with the first refusal of the case of a person who absolutely declined to enter hospital, quarantine, and as firmly declined to be revaccinated. A person fell ill with the disease in due course and was admitted to hospital." Mr BREMNER adds "It is incorrect to say that quarantine is carried out without recourse to vaccination and revaccination. True vaccination is not put into practice as it ought to be." It might have been hoped that when the sanitary authorities of a town had the courage to defy the experience and the united wisdom of the profession in the matter of vaccination they would at any rate be without fault in the matter of accommodation for isolation. Mr BREMNER's description of the building erected for small pox cases, then used as a scarlet fever hospital, with the reserve of a block for small pox patients ten yards from the western extremity of the main building, reads like a device for securing that the children affected with scarlet fever—unvaccinated children for the most part,

be it remembered—shall have small pox as well. This, at any rate, was the natural sequence of events. The following passage from Mr BREMNER's paper vividly records this fact as well as the advantage of vaccination.

"On Oct 31st, 1892, the hospital was more than full, containing 158 patients suffering from scarlet fever. Of this number eighty four were vaccinated, including those vaccinated by the medical officer of health. Of these eighty four vaccinated children not one contracted small pox. The remaining seventy four were unvaccinated, thirteen of these contracted small pox and four died. Small pox having broken out amongst these children, it became necessary to send the remaining scarlet fever cases to their own homes, where they were kept under observation and some of them were readmitted to the hospital suffering from small pox."

All this has occurred under the management of a sanitary authority who have been lecturing the country on isolation and sanitation with an air of superior knowledge and have been feeding an agitation which is threatening to relax the severity of the Vaccination Acts. It is idle to think that any system of notification or isolation can of itself protect unvaccinated persons from small pox. Both isolation and notification are interferences with "the life of a free people." Both will be evaded, especially under Leicester standards of the respect due to the laws of the land. Leicester itself is affording illustrations and is paying the penalty of lawlessness. Its sanitary authorities have set the example of disrespect to public law whilst thinking that laws of their own would be successful. We learn that already 140 cases of small pox in Leicester have occurred and 10 deaths (2 adults and 8 children unvaccinated). Of the 140 cases 83 were adults, 77 being vaccinated and 6 unvaccinated, 57 were children, 7 being vaccinated and 50 unvaccinated. These statistics should be read in connexion with the facts given in the letter of the medical officer of health of Leicester in THE LANCET of March 18th, showing the risk to the unrevaccinated members of the staff of the hospital. "Of these, 28 in number, 22 were protected either by a previous attack of small pox or by revaccination (including 8 whom I revaccinated), whilst the remaining 6 had been vaccinated in childhood, and so were not 'sufficiently' protected. Of these 6 inefficiently protected officials, all of whom refused revaccination which I offered them, 4 have since contracted small pox and 1 has died, so that 2 only of the staff now remain inefficiently protected and it will be interesting to note their future histories. The 4 recent additions to our hospital staff have now been revaccinated. One nurse, said to have been revaccinated ten years ago, has suffered from a doubtful and abortive attack of small pox." Here we leave this subject. Few can doubt that a wave of epidemic small pox is moving towards us that will endanger all unvaccinated children and all unrevaccinated adults and adolescents. The boast of Leicester anti vaccinationists has not increased their security, and the efficiency of revaccination is demonstrated by their own medical officer of health. If it so happens that the relaxation of the Vaccination Acts should be deferred perhaps even Leicester opinion may undergo a change, but this is a sanguine view.

THE first impression which a cursory perusal of the voluminous and intricate Bill that has been introduced by the Government for the purpose of completing what may be called the municipalisation of rural districts commenced by

the preliminary Act of 1888, gives even to a reader who is tolerably familiar with the matters with which it deals is that it is extremely difficult for anyone who does not possess such an acquaintance with what lawyers call the "purview" of the Bill to form any adequate idea of what its practical effect is likely to be. The leading feature of the Bill clearly is intended to be the parish council, and it is to this element that the hopes and criticisms alike of those who may be interested in it will be mainly directed. The creation and functions of district councils, consisting as they do in a great part of a mere transference to the new bodies of the organisation and powers of rural sanitary authorities and highway boards, will excite but little interest, as they involve only questions of administrative detail, but it is around the parish councils that the fray in committee on the Bill may be expected to gather. They are its *raison d'être*, and by the general outcome of opinion as to its provisions for their creation and powers it must stand or fall.

Upon the Bill as a general administrative measure for the completion of the scheme of local government initiated by the Act of 1888 this is not the place to offer any criticisms. Abundant artillery of this calibre will be directed against it as it passes the ordeal of committee by the numerous members of both Houses of Parliament, who are well able by their experience in the direction of local affairs to detect its weak points and to remedy its defects. Our object is to consider it from a purely sanitary point of view and in the light which a somewhat prolonged acquaintance with sanitary administration in rural districts may afford for estimating the effects which, if passed, it is likely to have upon sanitary progress in these localities.

The first remark which, in looking at the Bill from this point of view, it occurs to us to make is that, as a direct contribution to sanitary legislation, the Bill might just as well have not been brought in at all. From the title of the Bill to the end of the last schedule there is not one single word that adds in any degree to the powers of dealing with preventable disease, of abolishing its causes, or of remedying those innumerable defects in existing sanitary legislation by which the action of local authorities and their officials is hampered in contending with these evils. Unlike the Act of 1888, which, amidst a wilderness of non-sanitary provisions, contained a clause enabling county councils to appoint county medical officers of health—a power of which by the way, they have in but few cases as yet availed themselves—this Bill is throughout merely a scheme for organising, and in some degree for reorganising local administration. If therefore, the Government have any idea of claiming credit for it as a sanitary measure, it is just as well that, before commencing its discussion, they should be candidly invited, in the well known words of SYDNEY SMITH, to "clear their minds of cant."

Having said this much, we are the more willing to bear testimony to the important effect which the Bill may possibly have, if it become law, in indirectly promoting an interest in intelligent sanitary administration and in this way contributing to raise the standard of health in rural districts. Although we by no means share the optimistic views which are entertained by some of those who

have been helping of late to voice public opinion in favour of the need for parish councils, and as to the great things which are to be expected from them, we readily admit that the organisation of the parish, as the unit of sanitary as well as of all other local administration, is the indispensable foundation of any rational system of local self-government. It is only by giving local opinion in a parish the opportunity of what may be colloquially called "licking itself into shape" by means of a recognised organisation, invested with distinct powers and acting on a well defined programme, that the motor energy can be acquired which is essential in order to effect many sanitary improvements. It was urged as a justification of the Education Act that having enfranchised the working man it was next necessary to educate him, an argument, it must be admitted, which savours somewhat of the "cart before the horse" form of logic. So of the agricultural labourer as he is now politically the master of the situation, it is only right that he should have every opportunity of acquainting himself, not only with the objects and advantages of sanitary administration, but with the difficulties which attend it.

To take for instance an illustration from the most familiar of all forms of sanitary improvements—namely, drainage. Sub-section E of Clause 8 of the Bill empowers a parish council "to deal with any pond, pool, open ditch, drain or place containing or used for the collection of any drainage, filth, standing water or matter likely to be prejudicial to health." Now, parenthetically, it may be remarked that the word "deal" which is here used is not deficient in that sort of ambiguity by which the framers of Acts of Parliament so often seek to avoid committing themselves to intelligible precision. How a body which is limited to an expenditure not exceeding one penny in the pound for the financial year is to "deal" in any sense except a perfunctory one with nuisances of this description, which frequently can only be dealt with, in the sense of abating them, by considerable outlay, it is not easy to see. But let that pass, and let us assume that the way in which the parish council would deal with such a matter would be by presenting a scheme for its abatement to the district council. Now here is exactly the point where the educational influence of the parish council will soon be felt. The primary idea of most people, whether parish councillors or not, in regard to nuisances of this description is to pass them on to their neighbours as it were, and as may be by laying a drain to carry them off, with a punctilious indifference as to who is to pay for the drain and as the nuisance becomes of the "nuisance" when, as it is called, non by itself. Tomlinson it gets to the other end of the drain. Then the parish councillor will now have to make himself more fully acquainted than he has hitherto in his unincorporate capacity had an opportunity of doing, with the difficulties involved in dealing with drainage effluents and with the virtues of a system of dry conservancy carried on upon his own premises.

That the opportunity of thus educating himself in these and other practical measures connected with his own physical and social improvement cannot fail in time to be attended with beneficial results to parish councillors and their constituents alike, a man must be very blind or very bigoted to deny. But that the parish council is going to effect any very sudden amelioration of rural life it may be permitted to those of us who know something practically

about rural parishes to doubt. For what, after all, will the Parochial Council of the Bill of 1893 effect which could not be compassed by the Parochial Committee of the Public Health Act of 1872? That Act gave a rural sanitary authority power to delegate the whole of its powers, if it felt disposed to do so, for any parish in its district, to a committee of ratepayers living in the parish selected by itself. No power could be wider, no guarantee for getting an effective body together could be more complete, inasmuch as it was possible for the authority to put any person upon the committee who was likely to take an interest in its work. And what have been the results of the exercise of that power? So far as we can judge they have been very small. Here and there a parish committee has done good work and has fully justified the advice which called it into existence, but in the majority of cases it has more or less rapidly become effete, the victim either of intestine dissensions or of a sort of creeping paralysis of all its energies. It may, perhaps, be contended by the advocates of the present Bill that parochial committees have failed where parish councils will succeed, because they have, as a rule, ostentatiously abstained from seeking the coöperation of the very class whom the latter bodies are expected to attract. But here we are trenching upon the ground of very hypothetical considerations with which we need not now further deal.

There are numerous problems of this character, as well as of a more practical kind, connected with matters of organisation and administration, with which the Bill bristles, and which will doubtless be thoroughly threshed out when it gets into Committee. It is inevitable that the draughtsmanship of such a measure should, notwithstanding the great experience which must be brought to bear on it by the officials of the Local Government Board, be attended with obscurities, even to those who are pretty familiar with the subjects with which it deals. But, in spite of all the criticisms to which it may be subjected—and they will certainly be both numerous and weighty—it must be admitted to be a valuable contribution to the edifice of a national system of local sanitary and general administration, the foundation stone of which was so ably laid by Mr STANSFELD in the Public Health Act of 1872.

In conclusion, it may perhaps be well to say, for the information of our readers who are personally interested in the subject of health in sanitary work, that there is not a single parish in which directly affects vested interests, except in relation to those portions of sanitary districts created in two or more counties. There can be no doubt that the creation of parish councils will tend materially to increase the duties of county councils, and it is difficult to see how these bodies are to grapple with much of the work which will be thus thrust upon them without the assistance of a skilled medical officer of health. Those bodies who have not yet availed themselves of the power given them for the purpose by the Local Government Act of 1888 will therefore have an additional incentive to do so, of which it is to be hoped that, in view of the good results which have attended the county appointments already made, they will not be slow to take advantage.

Annotations.

"Ne quid nimirum"

MEDICAL AID ASSOCIATIONS AND THE GENERAL MEDICAL COUNCIL

At a National Conference of Friendly Societies held at the Foresters' Hall, London, on March 29th, it was resolved to memorialise the General Medical Council of the United Kingdom with regard to the action taken by certain members of the medical profession respecting these societies and the demand that had been made that the governing body of the profession should stigmatise as "professionally infamous" those registered practitioners who had accepted engagements with these associations. Mr Ballan Sted, who moved the resolution, asserted that the success of these institutions had brought upon them a most unjust charge from certain dissatisfied members of the medical profession. The General Medical Council may be trusted to consider with care the representations of the Friendly Societies on this important subject. At a Banbury Friendly Societies Medical Association banquet, presided over by the Mayor, this subject was alluded to in the toast of "The Medical Staff of our Association" by the proposer and by Mr Raye, the medical officer, who responded. Mr Raye called on the General Medical Council to deal with the question of unqualified assistants placed in branch practices at a distance from their principals and left with a book of blank death certificates signed by the principal. Mr Raye should have remembered that the General Medical Council has already dealt with this scandal and has removed the names of several practitioners from the Register for complicity in it. Mr Raye denied that there was increased mortality amongst the patients of the Medical Aid Associations. He made some dignified observations on medical etiquette and expressed his conviction that the General Medical Council would see justice done to such institutions.

THE TREACHEROUS SPRINGTIME

WE have been favoured lately with exceptionally bright and fine weather for the time of year. The month of March, 1893, divested itself entirely of its blustering, Leonine attributes and passed through its allotted period with a lamb-like placidity usually associated in our minds only with its closing days.

"Proud pled April, dressed in all his trim,
Hath put a spirit of youth in every thing."

and the "showery month" so far has not been true to that portion of its traditional reputation. The Easter holidays which have just passed will probably, with general consent, be considered to have been blessed with the most enjoyable weather experienced at this season for many years. Under these circumstances we fear that we may be thought to be pessimistic and unduly jealous of exercising the proverbial right of the Englishman to grumble when we venture to describe the present state of affairs meteorological by the heading of this annotation. In sober truth, however, a few words of warning may be most usefully addressed by our readers to their patients. We are so accustomed to read in poetic language of "gentle spring" and "ethereal mildness" that we are apt to connect the two, and to forget that such a springtime as we are now enjoying is full of pitfalls to the unwary and by no means free from danger to the most careful. The question of clothing, for instance, is a most difficult one. "Cast not a clout till May be out" is an undeniably wise saw as a general rule, but in weather such as the present it is attended by its disadvantages. A day on the river, a game of cricket, a ride on horseback or

on a bicycle, and even the morning walk to business and other forms of usually healthful exercise are apt, under the influence of a powerful spring sun and winter clothing, to result in free perspiration—an unmixed blessing if a change of clothes and a “rub down” are immediately available, but otherwise only too likely to result in danger to health. The sun’s rays, warm as they themselves seem, have not yet had time to warm the earth and so help to temper the chilling effects of a wind which has pretty surely at this period got “a touch of the east” or the north in it, and which, even if “south west,” is of a harsher nature than the gentle zephyrs to be expected later in the season. The invariable result is a prevalence of “bad colds.” We do not wish it to be thought that we advocate the reckless casting off of winter clothing. In that respect the perils of Charybdis would doubtless be greater far than the dangers of Scylla. What we would rather urge is the importance of recognising that a few bright days do not make summer, that we are still exposed to the treacheries of spring, in the lap of which winter lingers and as was recognised by the poet Goldsmith, himself a medical man, even

“Chills the lap of May”

It is wise therefore during the spring not to indulge in forms of exercise which involve anything in the shape of violent muscular effort unless adequate precautions are taken to avoid the results of chill.

PENSIONS FOR THE AGED

THE spirit of our age, whatever its defects, has not been wanting in purposes of benevolence. Examples of this tendency might be multiplied, but one will suffice for our present consideration. We refer to the series of schemes, as various as they are simple in their methods and colossal in their scope and enterprise, by which it has been sought to make provision for the aged poor. The subject has once more and quite recently been discussed in a paper by Dr Frederick Alderson. From this we learn that the writer’s preference is for a system of universal endowment by which the national purse would be taxed for the maintenance of all persons over sixty-five to the extent of 5s. weekly. He contends that so small a gratuity would not obviate prudent thrift but rather stimulate the recipient to its exercise. Filial piety would in like manner be rather encouraged than enfeebled. Non-payment of debts would disqualify the intending pensioner and thus honesty would be promoted in a matter with regard to which every medical practitioner has noted its frequent failure. Reference is likewise made in this paper to several other systems, partly provident, partly charitable, and resembling in their general outlines that above described. As regards approval of the essential principle upon which these are based—that of pity for the honest poor when incapacitated for work by age or illness—we should probably nowhere meet with any serious objection. It is when we come to ways and means that difficulties arise. Lord Halsbury said recently that the aged poor ought to be looked after by somebody, but this only raises a further question, Who is this somebody? Without professing to exhaust in discussion the stored logic of political economists, we seem to recognise, as the first and fittest incarnation of that somebody, the beneficiary himself. Whatever system be adopted, it is clear that the principle of self-help must play a prominent part in the creation of age pensions. In every other grade of life this rule holds good, and why not in that of the honest and prudent, though relatively poor, workman? We can see no reason why a trifling deduction should not be allowed on his weekly earnings and invested by way of premium for the expected pension, as in the case of Government salaries. One advantage connected with such a system would be its encouragement of steady working habits. Where the amount thus contributed did

not suffice for the purpose intended, a first additional charge would naturally come upon relations, and parochial consideration would thus be limited to cases in which misfortune or other exceptional cause necessitated special and discriminating treatment. We should like to see this question of pensions considered from a purely actuarial standpoint. So far it would seem as if the tendency is too purely charitable to be compatible with any rational estimate of the value of money. While sympathising, therefore, with the motive which inspires the various schemes above referred to, we consider as essential to its useful application the full recognition of two fundamental duties—namely, self-help and filial obligation.

STRONG OBSERVATIONS BY A JUDGE IN SUPPORT OF A MEDICAL PLAINTIFF

It is always gratifying to record the success of an action to recover honest and well-earned medical or surgical charges and the observations of an enlightened judge. This is our pleasure to-day in noticing the case of Mr Innes Griffin, medical officer of health for Banbury, who sued Mr James Humphries for the sum of £77s. for services to his son involving fourteen visits, trephining for a cerebral abscess in connexion with ear disease and two whole night attendances. At the last moment a defence was started of improper treatment amounting to slow diagnosis and to gross negligence except with regard to the operation, which it was admitted was well and judiciously done. The judge offered to postpone the case for further professional evidence to rebut the ungenerous theory of the defence. But the plaintiff’s counsel said the case was quite a clear one and elected to go on. The judge entirely approved the action of Mr Griffin and “assured him that he left that court with the same high and honourable professional reputation which he had when he entered it.” Asked about costs he said, “Certainly, costs on the higher scale and execution to-morrow.”

THE OUTRAGE ON KING HUMBERT

UNDER date Rome, April 1st, an Italian correspondent writes “Twice within his beneficent reign of fifteen years has the King of Italy been made the subject of violence or outrage on the public highway. On Nov. 17th, 1878, when driving in state through the Neapolitan streets, his life was attempted by a fanatic named Giovanni Passanante. In the same carriage with the King were his consort, Queen Margherita, the Prince of Naples (a mere boy) and the then Premier, Signor Benedetto Caroli, and, whether by mistake or by accident, the lethal weapon missed His Majesty and inflicted a severe wound on his minister, whose femoral artery it grazed, but providentially did not puncture or incise. Passanante, after his arrest, was made the subject of an elaborate medico-psychological examination by the well-known experts, Professors Tamburini, Buonomo, Tommasi and Verga, and their most interesting report given *in extenso* in THE LANCET (March 1st, 1879 pp. 321-2), which excluding all symptoms of mental neurosis in the would-be assassin found him a moral weakling, prone to fanaticism and the convenient tool of sinister agents in the background. He is now I believe, an inmate of the State Prison in the island of Elba, where, in solitary confinement, he has lapsed into complete dementia. Much less serious, though to the psychologist perhaps, more interesting, was the outrage aimed at His Majesty on Saturday the 25th ult. in the Villa Borghese. The king was driving that afternoon with his field adjutant when, near the first fountain, there was thrown at him a paper packet charged with refuse. The assailant was at once arrested, and on examination at the Questura turned out to be one Luigi Berardi, who represented himself as a believer in none but Jesus Christ and His vicar the Pope and a sworn enemy of the Italian Kingdom. Dr Pietro Malpieri

about rural parishes to doubt. For what, after all, will the Parochial Council of the Bill of 1893 effect which could not be compassed by the Parochial Committee of the Public Health Act of 1872? That Act gave a rural sanitary authority power to delegate the whole of its powers, if it felt disposed to do so, for any parish in its district, to a committee of ratepayers living in the parish selected by itself. No power could be wider, no guarantee for getting an effective body together could be more complete, inasmuch as it was possible for the authority to put any person upon the committee who was likely to take an interest in its work. And what have been the results of the exercise of that power? So far as we can judge they have been very small. Here and there a parish committee has done good work and has fully justified the advice which called it into existence, but in the majority of cases it has more or less rapidly become effete, the victim either of intestine dissensions or of a sort of creeping paralysis of all its energies. It may, perhaps, be contended by the advocates of the present Bill that parochial committees have failed where parish councils will succeed, because they have, as a rule, ostentatiously abstained from seeking the coöperation of the very class whom the latter bodies are expected to attract. But here we are trenching upon the ground of very hypothetical considerations with which we need not now further deal.

There are numerous problems of this character, as well as of a more practical kind, connected with matters of organisation and administration, with which the Bill bristles, and which will doubtless be thoroughly threshed out when it gets into Committee. It is inevitable that the draughtsman's ship of such a measure should, notwithstanding the great experience which must be brought to bear on it by the officials of the Local Government Board, be attended with obscurities, even to those who are pretty familiar with the subjects with which it deals. But, in spite of all the criticisms to which it may be subjected—and they will certainly be both numerous and weighty—it must be admitted to be a valuable contribution to the edifice of a national system of local sanitary and general administration, the foundation stone of which was so ably laid by Mr STANSFELD in the Public Health Act of 1872.

In conclusion, it may perhaps be well to say, for the information of our readers who are personally interested in the progress of health in sanitary work, that there is not a single parish in which directly affects vested interests, except in relation to those portions of sanitary districts situated in two or more counties. There can be no doubt that the creation of parish councils will tend materially to increase the duties of county councils, and it is difficult to see how these bodies are to grapple with much of the work which will be thus thrust upon them without the assistance of a skilled medical officer of health. Those bodies who have not yet availed themselves of the power given them for the purpose by the Local Government Act of 1888 will therefore have an additional incentive to do so, of which it is to be hoped that, in view of the good results which have attended the county appointments already made, they will not be slow to take advantage.

Annotations.

"Ne quid nimirum"

MEDICAL AID ASSOCIATIONS AND THE GENERAL MEDICAL COUNCIL

At a National Conference of Friendly Societies held at the Foresters' Hall, London, on March 29th, it was resolved to memorialise the General Medical Council of the United Kingdom with regard to the action taken by certain members of the medical profession respecting these societies and the demand that had been made that the governing body of the profession should stigmatise as "professionally infamous" those registered practitioners who had accepted engagements with these associations. Mr Ballan Stead, who moved the resolution, asserted that the success of these institutions had brought upon them a most unjust charge from certain dissatisfied members of the medical profession. The General Medical Council may be trusted to consider with care the representations of the Friendly Societies on this important subject. At a Banbury Friendly Societies Medical Association banquet, presided over by the Mayor, this subject was alluded to in the toast of "The Medical Staff of our Association" by the proposer and by Mr Raye, the medical officer, who responded. Mr Raye called on the General Medical Council to deal with the question of unqualified assistants placed in branch practices at a distance from their principals and left with a book of blank death certificates signed by the principal. Mr Raye should have remembered that the General Medical Council has already dealt with this scandal and has removed the names of several practitioners from the Register for complicity in it. Mr Raye denied that there was increased mortality amongst the patients of the Medical Aid Associations. He made some dignified observations on medical etiquette and expressed his conviction that the General Medical Council would see justice done to such institutions.

THE TREACHEROUS SPRINGTIME

WE have been favoured lately with exceptionally bright and fine weather for the time of year. The month of March, 1893, divested itself entirely of its blustering, leonine attributes and passed through its allotted period with a lamb-like placidity usually associated in our minds only with its closing days.

'Proud pled April, dressed in all his trim,
Hath put a spirit of youth in every thing

and the "showery month" so far has not been true to that portion of its traditional reputation. The Easter holidays which have just passed will probably, with general consent, be considered to have been blessed with the most enjoyable weather experienced at this season for many years. Under these circumstances we fear that we may be thought to be pessimistic and unduly jealous of exercising the proverbial right of the Englishman to grumble when we venture to describe the present state of affairs meteorological by the heading of this annotation. In sober truth, however, a few words of warning may be most usefully addressed by our readers to their patients. We are so accustomed to read in poetic language of "gentle spring" and "ethereal mildness" that we are apt to connect the two, and to forget that such a springtime as we are now enjoying is full of pitfalls to the unwary and by no means free from danger to the most careful. The question of clothing, for instance, is a most difficult one. "Cast not a clout till May be out" is an undeniably wise saw as a general rule, but in weather such as the present it is attended by its disadvantages. A day on the river, a game of cricket, a ride on horseback or

occasionally the successful worker must halt and return disqualified. We do not doubt that some such late rejections have been fully justified by the presence of actual disease however caused. At the same time it must be admitted that cases have occurred in which conditions of imperfect health, by no means important in themselves, have become so developed or aggravated or mere overstrains as to convey the impression of serious disability an impression which a few weeks or months of leisure suffice to dissipate. Here surely there is room for amendment of existing custom, and the appropriate remedy is not far to seek. No possible objection could be raised against such an alteration of established rule as would defer the date of this second medical inspection to a period considerably later than that of the ordinary examination of candidates. We should strongly recommend the adoption of this practice wherever it is not already in use. Any more speedy method, whatever its apparent advantages can hardly do justice either to the skill of the examiner or to the legitimate prospects or overstrained but still physically sound competitors.

DENTAL ADVERTISING

THE question how to deal with advertising has been a very difficult problem to solve in all professions and just now is largely agitating the dental world. The general opinion held by respectable dental practitioners and by the community at large is of course that it is most derogatory to the profession as a body and that those who practice advertising are 'quacks.' Mr. Blandy proposes that a petition signed by registered dentists shall be presented to the General Medical Council, praying them to make it a matter of 'infamous and disgraceful conduct,' which means erasure from the Register. 'If he conducts his practice by means of the exhibition of dental appliances or apparatus in an open shop or in a window or in a show-case exposed to public inspection, or if he seeks to attract a patron by means of public advertisements or circulars describing modes of practice, or patented or secret processes or by the publication of a scale of professional charges.' With regard to the expediency of the movement it seems to us very doubtful whether the General Medical Council has any power to move in the matter, and further, even if there is, whether the time is ripe to push it. It must not be forgotten that a large number of the registered dentists are still unqualified men and so are not under the control of any licensing faculty, but we think that it ought to be very strongly urged that all corporations granting a licence should insist upon a guarantee by the recipient of a declaration not to advertise. But the whole matter would be much more satisfactory if dental surgeons would take the trouble to become not merely affiliated with, but actual members of, the medical profession.

"HUMAN REMAINS IN THE CITY"

UNDER this heading the *City Press* of March 25th publishes the judgment of Dr. Tristram, Q.C. Chancellor of the Diocese of London, given at the Consistory Court of St. Paul's Cathedral on March 2nd, upon the application of the rector and churchwardens of St. Michael Bassishaw. This was to enable them to remove human remains from underneath the church. The faculty was granted and the remains will be removed to the Great Northern Cemetery care being taken to have the fact of the removal notified on a stone in the centre of the ground to be occupied by the remains and also in the vestry of the church. The Chancellor was careful to explain at some length that the order of the Home Secretary was not sufficient to ensure the removal of bodies from any church or consecrated burial ground without a faculty. No one appreciates better than we do the excellent adage *res auctor ultra crepidam*, and we have no wish to interfere with the duties of chancellors or any

other ecclesiastical dignitaries, but in all that relates to the public health we have a right to speak with authority, and as Dr. Tristram himself referred to the case of St. Botolph's Church, Aldgate, we may remind him that we felt bound at the time to enter our protest against the faculty which he granted to reinter human remains in the vaults under that church, a position which was supported by the sanitary authorities of the city and by the Home Secretary. Moreover, these remains were removed to a suburban cemetery, notwithstanding an attempt on the part of the church authorities to override the orders of the Home Secretary. The fact is that these faculties must be regarded as pure formalities. When the sanitary authorities have decided that for reasons of health human remains must be removed the faculty must perforce be issued as a matter of course and as a matter of form. Should a faculty be asked for to inter any bodies beneath a church it should be refused since no ecclesiastical authority can be justified in doing that which is dangerous to the public health. What has recently occurred at St. Mary's Woolnoth, St. Michael's Bassishaw and other churches should convince everyone of the danger of burying any human body beneath a consecrated building used for worship. Sooner or later mischief will result, and the only effectual remedy is to remove the body to some suburban cemetery.

PREVENTIVE MEDICINE AT OXFORD

OUR oldest University has at last awakened to the necessity of taking part in the progress of preventive medicine, and of rendering her degree in Public Health less exclusively restricted. Following the wake of Cambridge, this is now proposed to be open to all registered medical practitioners. A statute embodying this important change will be promulgated before Congregation on May 2nd next. There is to be an annual examination by four examiners presided over by the Pegasus Professor of Medicine. The subjects will comprise (1) General Hygiene, (2) General Pathology, with special relation to infectious diseases, (3) Laws relating to Public Health, (4) Sanitary Engineering, (5) Vital Statistics. Every candidate must have been registered for a twelve-month, must have spent six months working in a Public Health Laboratory and another six months as assistant to a health officer of a town or county of at least 50,000 inhabitants. We trust that the statute will meet with no opposition, and that the Oxford Diploma in Public Health may be eagerly sought after and confer the same distinction as the other degrees of this University.

WELLINGTON COLLEGE

THE appointment of Mr. Pollock, assistant classical master at Marlborough, to the headmastership at Wellington College in succession to Mr. Wickham, who will vacate the position at the end of the forthcoming term is an occasion of which the governors of Wellington College have availed themselves to announce to the public and the parents of boys, present and prospective, the sanitary improvements which they have endeavoured to effect, regardless of cost, under the direction of Mr. Rogers Field, the well-known sanitary engineer. Nine years ago we opened the question of the insanitary condition of Wellington College. In the correspondence that then took place it appeared that the governors' attention had been called to the subject some years previously by the medical officer of the College, but without avail. Differences of opinion existed between the governors and Mr. Wickham, the headmaster on the one hand, and Mr. Barford, the medical officer on the other, not only as regarded the insanitary surroundings of the College, but also as to the local origin of the diseases which prevailed amongst, and proved fatal to some of the boys. We opened our columns freely in the interest of the

went minutely into his case and elicited facts that left no doubt that he was a madman of the type known to Italian classification as *megalomania religiosa*, which includes the hallucination of 'persecution.' There was a family history of neurosis, physical and mental. His father died an epileptic. His sister has been an inmate of a lunatic asylum for six years. At the age of nineteen, in an explosion of fury at an employer, he bit the latter so severely as to cause his death in hospital a few days after. For this he was condemned to seven years' solitary confinement at Orvieto. On his release in 1833, he was again imprisoned for 'cutting and wounding,' and after serving a short term of incarceration, he emigrated to New York, where he seems to have been an inmate of the lunatic wards of the public prison. Returning to Italy at the end of last year he led a 'persecuted' life in Rome, which culminated in the outrage on the king on the 25th ult. Since his arrest his religious exaltation has assumed the form of self-imposed abstinence from food, whilst he declares himself superior to the 'Vicar of Christ.' In all this we have a striking example of the looseness with which the criminal law is administered in the Italian peninsula, and of the levity with which dangerous lunatics, liable to epileptoid explosions, are allowed to be at large. Had Berardi been more vigilantly looked after during his first imprisonment he would never have been allowed to mingle freely in sane society, and the violence of which from time to time he was the perpetrator would have expended itself harmlessly within his place of confinement. In other countries the risk of letting epileptics engage in service, public or domestic, has of late been but too painfully realised, but in Italy its exemplification is so frequent as to call for State intervention. She holds an evil pre-eminence in 'impulsive homicide,' the authors of which, young and old, but especially young, fill her *bagno* to overflowing. Again, what in England would be called 'suicide while in a state of insanity,' is amongst Italians looked upon as quite a reasonable act if weariness of life or '*dissesti finanziari*' (money difficulties) or disappointment in love or '*gelosia*' (jealousy) are strong enough in the victim. But English jurisprudence is sounder than Italian in these cases, and, as a Milanese contemporary shows us, the 'epidemic of suicide,' as it calls it, which has saddened the columns of Italian journals for years past, ought to be probed to its root and traced to a mental neurosis as marked as it is wide spread. The subject, I am happy to note, will come before the International Medical Congress in authoritative guise next September, by which time we are but too likely to have many more cases like Berardi's of 'dangerous epileptics at large,' or of that impulsive self-murder which a more rigid surveillance of neurotic youth might have prevented betimes."

"EVIDENCE OF THE CAUSE OF DEATH"

SUCH is the title of a pamphlet by Mr E. L. Hussey, coroner for the city of Oxford, consisting of twenty-two pages. It is addressed to a "Brother Coroner," as would seem from the context, partly as an expression of opinion of Mr Hussey's general views of coroners' law, and partly as a homely advice to the addressee. The work does not readily lend itself to regular criticism, seeing that it is rather a collection of paragraphs of mixed nature than a logical examination of propositions. Reading between the lines, however, we are able to gather that the writer does not stand on common ground with the majority of medical practitioners. The argument seems to be directed against the calling of medical witnesses and the ordering of post-mortem examinations in all cases where the exact cause of death is equivocal. In more than one illustrative case the writer, as it appears to us, assumes an attitude of antagonism to himself. This is notably so where, on page 21, he cites the facts as deposed to at an

inquest on a man who locked himself up in a room, was heard to groan, and on the door being broken open was discovered dead. A friend of the deceased and a medical man who accompanied him found in the bedroom a glass containing fluid "which seemed to them beyond doubt to be a solution of strychnia." The practitioner who attended the deceased was not called. It does not appear that an analysis of the contents of the glass was made. There was no post-mortem examination of the body. We ask, then, was the theory of suicidal strychnia poisoning, or strychnia poisoning at all, as embodied in the verdict of the jury, warranted by the testimony? And yet this case is given as a type of legal, medical and common sense procedure. Whilst giving the writer all credit for the best intentions and admitting that neither on logical nor scientific grounds is it necessary to hold an inquest in every case of death under an anæsthetic, we still maintain that such a course is not only desirable but necessary to exculpate the anæsthetist and the surgeon and to satisfy the patient's friends. It is scarcely necessary to examine in detail the writer's views of chemical nomenclature, suffice it to say that they are not quite in accord with those adopted in standard works. A long list of popular expressions relative to causes, consequences and symptoms of disease is given. Mr Hussey considers these terms "sufficient" and intelligible for the cause of death. Here we join issue, for in our opinion they are not all of them intelligible and consequently not "sufficient." On previous occasions we have insisted that whenever the cause of death is doubtful a post-mortem examination should be made, and, if necessary, a chemical analysis, and our opinion is not shaken after perusal of Mr Hussey's pamphlet. Of course, there are cases of death from violence where the demand for medical evidence would be simply vexatious.

THE MEDICAL ELEMENT IN COMPETITIVE EXAMINATIONS

SINCE the time of its institution the competitive examination has entailed upon all concerned with it almost as much anxiety as benefit. As a gauge of amassed information it is probably unrivalled, as a test of latent energy in the form of knowledge its value is at least open to question. After all, however, it must be allowed that no alternative system has yet been suggested as adapted to fulfil with equal efficiency the purpose of selection which called it into being. We must, therefore, it would seem, still bear with its drawbacks for the sake of its advantages. The great vice associated with the system is of course the necessity of cram which it involves. Out of this arise most, if not all, of its other defects. For the present we need not deal with the question in its literary aspect. There are other and physical considerations which are sometimes of even greater importance to the individual student competitor. It is in obedience to no mere professional fancy that medical inspection forms an important part of such examinations, since it is clear that health and character have at least as much to do with the actual utility of passed candidates as education itself. Health, indeed, is of these the more critical matter in this that it cannot be regulated by mere will or by considerations of expediency. It can only be guaranteed by personal examination and the circumstances under which this is conducted are of the first importance. It is a wise rule which provides that a candidate shall, before entering himself for the contest in mental culture, present a certificate of sound bodily health. He is thus afforded some sort of guarantee that his studious labour, if allowed at this stage, will not end in disappointment on the score of physical conditions. Alas for human hope, illness and accidents do not respect the set stages of competitions and therefore a still later barrier of medical inspection is indispensable. Here-

energetic efforts of the medical officer, Dr Priestley, seconded by his experienced chief sanitary inspector, have done much to minimise the risks of infection from households, although their members could not be actually confined in one place. We are glad to observe that Mr Clifton, the chairman of the special committee—the premature publication of whose report was latterly complained of by Mr Windley—fully recognises that some modification must be made in the manner in which the principles of prevention of dissemination of small pox are to be carried out. Leicester, having chosen to abandon vaccination, is bound to render its provisions for isolation as perfect as possible, and although it may suit the purpose of some of its authorities to attribute the present visitation to an unavoidable extension of the disease in a building wholly unsuited for the purpose, they have much to answer for in subjecting unprotected children to the chances of infection which the most careful precautions can in that case hardly obviate.

POISONING BY TINNED BEEF

A FAMILY residing at Chelmsford partook of some American corned beef for breakfast on the morning of Wednesday, March 27th. The meat was observed to be slightly moist on the surface and did not drop out of the tin readily. It is also stated that the meat had a "spicy" flavour as of thyme. The mother, who is an elderly lady, about an hour and a half after breakfast complained of feeling giddy, and shortly afterwards persistent vomiting supervened followed by cramps, spasm and diarrhoea. The father, son, daughter and a maid servant were attacked shortly after, and for a time the life of the son was despaired of. All have now recovered. Unfortunately the remaining meat was destroyed. This, of course, is to be regretted, as in all such cases the unconsumed portion should be reserved for chemical and bacteriological examination. When examined a few days later the under surface of the tin was found to be corroded considerably more than was the case with other tins which had been kept a much longer time. In the scrapings of fat from the side of the tin both lead and tin were detected by Dr Thresh. The symptoms, however, were undoubtedly those of ptomaine poisoning.

SOME LESSONS OF SUICIDE

Few of the misfortunes which can overtake a man are able so to overwhelm him that they do not leave open some avenue of hope, and the more especially if they are not attributable to conscious error on his part. The mind so conquered by depression that it cannot see this outlet is therefore surely unhealthy. It may doubtless be free from other ordinary signs of persistent and confirmed insanity, but it illustrates, nevertheless, a condition of weakness which in the grosser bodily fabric would pass for disease. Its disorder is not less a malady because it is often transient and is not related to known organic changes. In it we recognise the close connexion between rational and moral qualities, and it is the failure of both, but especially the latter to influence their unfortunate possessor which is so grimly taught by suicide. Despair is the true exciting cause of such calamities, and thus we take it is nothing else than moral short sight. We are all of us liable to suffer from it, and, though for the most part we know it only as a temporary disturbance of function, each of us can attest its prostrating influence and the strength of its resistance to the curative powers of reason and of faith. The case of a lad who lately poisoned himself with chloral hydrate because he failed to pass the entrance examination at the Durham Medical School was peculiar only in its secondary details. Naturally delicate, oversensitive and over anxious, he was stunned by his disappointment—and he died of this disease. Who has not known, like him, the

infinite discomfort of a seemingly unbearable present and impossible future. Yet there is no truth more certain than that which tells us that everything comes to the patient hope which knows how to wait. It is in the possession of this divinely planted quality that we have the surest remedy for all those miseries of distrust which culminate and are by some believed to end with self-destruction. There is a subsidiary question of some interest connected with the case above mentioned. How came the unhappy boy to have about him a fatal dose of chloral? There was no evidence of the medicinal administration of this drug. We are, therefore obliged to conclude that it was, as it easily might be, purchased of some neighbouring druggist, and the fact of its prompt and purposeful misuse affords a fresh reminder of the far from adequate restriction placed by Government upon the sale of poisonous remedies.

INFLUENCE OF THE SYMPATHETIC ON THE EYE

HEESE has contributed to *Pflüger's Archiv* an important paper dealing with this interesting question, and an abstract of it appears in the last number of the *Neurologisches Centralblatt*. The question of the existence of a special dilator muscle for the pupil has long been a vexed one. The effect of the sympathetic in causing dilatation has been ascribed to contraction of the iris vessels by some, and to an inhibitory influence on the sphincter of the iris by others. Heese claims, by experiments on the cat, to have demonstrated the existence of a special dilator of the pupil. He has also investigated the mechanism of protrusion or retraction of the eyeball. These, he says, depend, firstly, on the condition of contraction of the bloodvessels of the orbit, and, secondly, on the contraction of the orbital muscle. Both are innervated from the cervical sympathetic. The influence of this is strongest on the orbital muscle, so that stimulation of the sympathetic causes protrusion of the eyeball. In the rabbit, however, the vaso-motor influence is predominant, and stimulation of the sympathetic in this animal by contracting the orbital bloodvessels causes retraction of the eyeball.

THE GRESHAM LECTURES ON PHYSIC

WHEN Sir Thomas Gresham founded what he fondly hoped would constitute the basis of a real University of London he could hardly have imagined that his College would in course of time be given up to popular instruction in the art of medicine and surgery. The present Gresham Professor of Physic has held office for many years and has doubtless been often exercised to find suitable topics for his elementary instruction of the laity. That he may have sometimes erred in his selection is but natural, but at least he may be expected to exercise some judgment in the matter and avoid trenching on topics which can only be properly appreciated by those who have had a medical training. The syllabus of the next course of lectures which he is to deliver lies before us, and we observe with deep regret that Dr Symes Thompson has, unwittingly we believe, transgressed against one of the cardinal principles of the College of Physicians, of which he is a Fellow. The course is to be devoted to the nose and mouth, subjects which doubtless admit of popular treatment and afford scope for the introduction of much useful and homely advice. Whether his audience will be able to appreciate all the topics included in the third lecture, in which he is to treat of the "Nose and Mouth in Health and Disease" may be open to question, and it speaks volumes for his proficiency in the art of lecturing that he should feel able to convey an intelligible view of the subject within the space of one hour. It is however in the scheme of the fourth and concluding lecture that we think Dr Thompson has overstepped the limits which his

College, as we thought, not only at the time but on subsequent occasions, till at last public opinion was sufficiently directed to the matter and the governors could no longer postpone giving their attention to it. The College has suffered, not only by the death of some of the boys and one of the most valued masters, but by the serious and widely spread illness of others, necessitating the removal of the whole school for a time. Nor are these the only evils that have arisen. Those of our readers who are interested in Wellington College can easily see for themselves the ill effect this long impairment of health has had on the scholarship of the boys by referring to the "Public School Record" in the *Pall Mall Budget* of Dec. 8th, 1892. Mr Rogers Field in his report¹ congratulates the governors on the sanitary improvements he has been permitted to effect regardless of cost, which he considers make "Wellington College one of the best, if not actually the best, in regard to the completeness and excellence of its sanitary arrangements" as compared with similar institutions. We hope Mr Rogers Field will not be doomed to disappointment. It would have been better for the reputation of the College had a comparison been made between the sickness of the past and preceding terms with those of previous years in order to show if there had been any decided lessening of sickness amongst the boys since Mr Rogers Field's improvements have been in operation. Confidence in the institution has been shaken, as is proved by the falling-off in the number of the pupils. If the governors wish this to be re-established they must give proof that the works have had the desired effect in making the boys less liable to sickness and more vigorous in work, as health is as essential to work as work is to scholarship, for, according to the "Public School Record," in entrance scholarships at the universities Wellington College is below all other public schools and below most of the grammar schools which aim at university distinction. It is no small undertaking for the newly appointed headmaster to rectify this and we wish him every success.

THE QUEEN IN FLORENCE

UNDER date April 3rd a Florentine correspondent writes "Queen's weather in the City of Flowers—as near a definition of the earthly Paradise as can be given—continues to characterise Her Majesty's vernal *villeggiatura*. The cloudless skies, the brilliant sunshine, the crisp, restorative air just freshened, but not chilled, from the snow wreaths above Vallombrosa and on the Pistoiese Apennines, make out-door exercise, whether for the pedestrian or the carriage inmate, a highly agreeable function, appreciated as it fully is by crowds of foreign residents who, for the time at least, have rendered Florence something like a suburb of London, of Paris or of Berlin, or rather of all three combined. Queen Victoria has visibly improved in health since her arrival on the 23rd ult. and greatly enjoys the 'still life' of the Villa Palmieri, with its opportunities for quiet little excursions into the rural neighbourhood and the exchange of kindly greetings on the hill sides with the simple country folk and their little 'hostages to fortune.' The loyal self-suppression with which the Florentines comport themselves under very strong temptation to the contrary leaves Her Majesty all the privacy she wishes, and doubtless enhances her sense of release from the 'cares that link with empire' and from the 'monotonous uncertainty' of a spring in the British Isles. Many of the public demonstrations at which the Queen was expected to assist have had to dispense with Her Majesty's intervention, the Princess Beatrice acting in her stead and acquitting herself with a gracious cordiality and effect which have won the hearts of the Florentines. One of these occasions was the distribution of prizes at the Circolo Filologico to those of

the public—the cabmen and coach hirers particularly—who had responded best to the regulations of the Society for the Prevention of Cruelty to Animals, and the interest shown by Her Royal Highness in the kindly treatment of the dumb servants of society cannot but react favourably on a movement to minimise the maltreatment and the sufferings of the brute creation and to humanise its often cruel and all too negligent masters. The great event of the week is the bazaar in aid of the reconstruction of the Church of the Holy Trinity, the increasing attendance at which has rendered its accommodation quite inadequate to the yearly augmenting demands of the British community. Here, again, the Princess Henry of Battenberg will represent Her Majesty the Queen and impart, it is anticipated, a spirit to the sale and a success to the enterprise which must accelerate the consummation it is intended to promote. Even more than on the occasion of Queen Victoria's former visit, Her Majesty's presence in Florence will give a manifest and enduring stimulus to the efforts of its leading inhabitants to improve the conditions, sanitary and social, under which they live, and will effectively reinforce the endeavour of the Duke of Aosta, who represents the King of Italy in the central city of the peninsula, to restore to it the prestige and the attractiveness which it has not quite maintained since it ceased to be the capital of an Archduchy. I may add that Florence has never been so full as during this week, and that with the ever increasing influx of the foreign element on which its prosperity relies the municipality will be encouraged in the matter of water supply, of drainage and of 'nettezza pubblica' (tidiness of the streets) so to improve on tradition as to silence the sanitary censure, all too justified by its past, and to replace some of the more formidable deterrents by real attractions to the passing visitor or to the permanent sojourner within its gates."

THE "LEICESTER SYSTEM" OF TREATING SMALL-POX

THE article contributed to the columns of THE LANCET by Mr Bremner,¹ which, to our thinking, showed conclusively that, in respect to provision for isolation and inspection, Leicester has no claim to any special superiority over other towns, and in which, too, it is proved that the so called "system," so far from being economical, as its advocates were wont to assert, is necessarily costly in proportion to its efficiency, has naturally aroused some indignant replies from those who have been for many years responsible for carrying it out. The matter was brought before the Town Council on the 27th ult. by Mr Alderman Windley, the chairman of the Sanitary Committee, of which Mr Bremner is a member. The chairman spoke warmly, but the fact that he should have felt it needful to speak at all says much for the state of disunion that exists amongst those responsible for the health of the town on this matter. Mr Windley explained that the cause of the outbreak in the fever hospital was due to an error of judgment on the part of the medical officer, but he did not tell the Council that the ill results of such an error would not have occurred at all had his committee had the foresight to provide sufficient accommodation for the isolation of doubtful cases. As regards the main question we cannot see that Mr Bremner's version differs materially from that of Mr Alderman Windley. The plain fact is, as we point out elsewhere, that Leicester, confident in its security by the adoption of "quarantine" as the chief means for combating small pox, was unable to carry it out on the original lines from mere lack of accommodation. The essence of the "Leicester system" is the removal of members of infected households to "quarantine," and since that has not been carried out during the past three months it has failed. Nevertheless, the

¹ The Times, March 24th, 1893.

² THE LANCET, March 25th, 1893.

food, either in water or in earth. (2) The spread of influenza and epidemic can occur but seldom. (3) Infection is as a rule, effected by means of the still moist secretions of the air passages. Dr Pfeiffer considers the catarrhal form of influenza to be by far the most frequent. In mild cases scarcely to be distinguished from ordinary catarrh, he found the bacillus in enormous numbers in the secretion of the nose, whereas in cases of simple catarrh the secretion is almost sterile and certainly contains no bacterium to be mistaken for the influenza bacillus. During the acute stage the bacillus is present in the expectoration in large numbers. It sometimes persists in it for weeks or even months thus explaining those cases of prolonged convalescence which have been noted especially amongst tuberculous individuals. The general symptoms are to be regarded as the result of the absorption of influenza toxine. The bacillus may reach the pleura and there excite a pleuritis. No animal is known to be spontaneously affected by influenza. Guinea pigs are very susceptible to the influenza toxine, exhibiting symptoms of fever, dyspnoea and extreme muscular weakness, strikingly resembling the clinical appearances in man. In conclusion, Dr Pfeiffer points out the importance of thorough ventilation in all places where many people are assembled, such as theatres, schools and barracks since every cough or sneeze expels infectious material into the air. He further suggests the use of disinfecting washes for the nose and mouth and the inhalation of antiseptic vapours and concludes by expressing the hope that the knowledge of the cause of this remarkable disease may lead to the discovery of a specific remedy.

TUMOUR OF CENTRUM OVALE

In the last number of *Brain* Dr Landon Carter Gray of New York relates a case in which a tumour in this situation gave rise to paralysis of motion and muscular sense. The patient was a man aged thirty-eight, whose left leg and arm had gradually become weak about a fortnight before he first came under Dr Gray's observation. Coincidentally with the onset of weakness the patient had suffered from headaches and a certain amount of insomnia. The only significant points in his previous history were an attack of what was apparently Ménière's disease some years before, which had been succeeded by permanent deafness in one ear and the occurrence of an abscess in the region of one knee. This had been removed by means of caustics. About a year before the symptoms of cerebral trouble began a hard nodule had appeared in Scarpa's triangle and had gradually spread so as to involve the whole of this anatomical area. The patient had never suffered from any convulsion or loss of consciousness. There was no distinct syphilitic history but iodide of potassium had been administered. It was borne so badly, however, that it could not be persevered with. On examination there was found to be considerable loss of motion in the right leg and also in the arm. In the foot sensibility to tactile and painful stimuli was slightly impaired, but the temperature sense was normal, the muscular sense, both in the fingers and foot, was very much impaired. There was no affection of the face or tongue, the ocular muscles were not affected, and there was no optic neuritis. A diagnosis of subcortical tumour was made. A fortnight later the paralysis had advanced, so that the right leg was completely paralysed, and in the corresponding upper limb only slight movement of the fingers was possible. Sensibility to touch and pain in the right hand was now distinctly affected, the face and tongue were still free, but the headache had become intense. Intelligence and speech were unaffected. On being reclined the dura mater bulged very much, but was otherwise normal in appearance. No tumour was found, although the brain was punctured in various directions. The patient became comatose very soon after the operation and died three days later. At the necropsy the calvaria was found to be

unusually thick and there were inflammatory changes at the seat of operation. On making vertical sections of the brain from before backwards, and examining them carefully, a neoplasm about the size of a "hickory nut" was found in the ascending parietal convolution, in the neighbourhood of the posterolateral extremity of the convolution, and situated about a quarter of an inch beneath the cortex and about the junction of the upper and middle third. This was cystic in the centre and on microscopic examination was found to be a small round-celled sarcoma of the melanotic variety. The nature of the tumour in the leg is not stated, but the case illustrates the possibility of the existence of loss of muscular sense with the almost complete retention of sensibility to ordinary tactile, painful and thermal stimuli.

LIBEL ACTION BY A SURGEON

At the recent Birmingham Assizes before Lord Justice Bowen, Mr F. R. A. Evans recovered damages to the amount of £75 against the proprietors of the *Birmingham Daily Post* for an article written in December 1889 in reference to the trial of the plaintiff for the manslaughter of a woman during her confinement, in which the plaintiff was acquitted, the judge describing the prosecution as vindictive. The judge said it was remarkable that the plaintiff did not complain till three years after. Such actions are just and we rejoice in their success, but they should be taken soon after the alleged injury.

OUTBREAK OF TYPHUS FEVER IN TRIPOLI

ONE of those epidemics which in subtropical latitudes make the nearest approach to the mediterranean plague has broken out in the Ottoman pashalik of Tripoli and has already caused great mortality, particularly in the plateau of Barca. From the imperfect details that have reached us the symptoms appear to be those of typhus fever—that is of a continuous prostration with grave disturbance of the nerve-centres inducing muscular lethargy and mental hebetude, and with an exanthematous display of spots red or livid, about the fifth day from the beginning of the fever. The immediate causes of this explosion are also withheld but are not far to seek. In Tripoli the population lives poorly, trade has for some time been depressed, and to the extent of lowering influences must be added, in the plateau of Barca, the noxious custom of burying the dead within a few inches of the surface of the soil. This latter usually sandy and always light and friable, had for weeks been inundated with heavy rains so that the scanty covering of earth was washed from above the corpses and pestiferous exhalations were the necessary consequence. In these circumstances the epidemic has made rapid progress, one fifth of the inhabitants (who number about one million in all) have been struck down, a large proportion, amongst them the governor of the province, have died, and still the malady gives no signs of abating. A correspondent writes 'The panic is indescribable, the law courts are shut, the shops are deserted, all business is at a standstill, and the European population is in full stampede.' We await a duly authenticated medical report of the epidemic and have but to hope that it may not spread to the Mediterranean ports with which Tripoli is in frequent communication—particularly Tunis, Alexandria and Malta.

DEATHS OF EMINENT FOREIGN MEDICAL MEN

THE deaths of the following distinguished members of the medical profession abroad have been announced.—Dr David Wiener, author of a 'Manual of the Medical Laws of the German Empire,' at the age of sixty-seven, at Graudenz.—Dr Adolf Fischhof, formerly a well known Vienna practitioner. He took part in the "March Move-

office imposes on him, and the best way to indicate this will be by quoting this part of the syllabus in full —

"Treatment of Disorders of Nose and Mouth — Prevention of Chronic Catarrh of Nose, Throat, Ear &c., Polypi and Alteration in the Nasal Bone, Electrical and other Remedial Treatment of the Tongue and Throat, Use of Caustics and Medicaments to Palate and Lips, Treatment of Hare lip and Cleft Palate."

It is a pity that Dr Symes Thompson should fail to see that no useful purpose can be served by dealing with such topics as these in a public discourse and that he should mar the good work of instructing the laity in the principles of health, which he has so often undertaken, by the introduction of details of medical and surgical treatment the full bearing of which can only be appreciated by professional men.

ABUSE OF LONDON DISPENSARIES

THE *City Press* reports the opinion of a medical man—the medical officer of a London dispensary—that London dispensaries are much used, that is, much abused, by those who can afford to pay. This gentleman was struck with the well to do appearance of a man with a free letter. On inquiry, he turned out to be a foreman and earned regularly upwards of 50s a week. Such a patient would scarcely be a fit member of even a provident dispensary. He would be excluded by the rules of so good a provident dispensary as that of Northampton, which provides that no shopkeeper or foreman in a factory can become a member. It is a fraud for such a man to appear with a free letter at a charitable institution, the blame of which must be shared between him and the subscriber who gave him the letter. Our city contemporary does good service by publishing such facts.

PREVALENCE OF FEVER

DURING the week ended March 25th scarlet fever showed somewhat greater prevalence in the large towns of the kingdom compared with that during the former week. More than 1000 cases were notified, London supplying about 400 of them, next came Sheffield, West Ham, Leicester and Liverpool. Some 300 cases of diphtheria were reported, London contributing more than half of them, West Ham and Cardiff coming next. Of the total number of cases of enteric fever reported the metropolis furnished little more than a fifth, Liverpool and Birmingham the next largest number. It is reassuring to know that, though scarlet fever incidence in London has not diminished, the mortality from this disease has declined, the deaths from scarlet fever having been last week below the average. Though more cases were admitted into hospital the numbers remaining under treatment are about the same. The diphtheria mortality, though considerably less during the week, was yet greatly above the average. More cases were admitted and more remained under treatment. It is gratifying to be able to record that the influenza mortality is distinctly less.

SOCIETY FOR THE STUDY OF INEBRIETY

SIR WILLIAM CHARLEY, Q.C., D.C.L., late Common Serjeant, read an elaborate paper on the "Inebriates Acts, 1879 and 1888. Ought we to amend them?" at the annual meeting, held in the rooms of the Medical Society of London, on the 4th inst., the President, Dr Norman Kerr, in the chair. The learned gentleman accepted the definition of inebriety as a disease closely allied to insanity and recognised the right and duty of the State to provide curative detention for inebriates of all classes. He showed that in the Bill drafted by him in 1877 the reception of inebriates by a retreat was a comparatively simple matter, the request for admission requiring attestation by only one justice or by a commissioner to administer oaths in the Supreme Court. The only mode of admission at

present is by appearance before two justices, which deters many applicants. Sir William Charley had also provided for the reconveyance to the retreat from which he had escaped of any fugitive under the Acts, whereas the existing law necessitates the intervention of a justice's warrant and apprehension of the escaped patient by the police. Dr Dalrymple's Bill of 1870 proposed to empower guardians to detain inebriate paupers for treatment. In the 1877 Bill Sir William Charley provided for compulsory seclusion by justices in Petty Session, but he now preferred the Victorian authority of a Master in Lunacy or a County Court Judge on the production of two medical certificates. Sir William Charley endorsed the dicta of Drs. Dalrymple and Norman Kerr on inebriety as a disease demanding therapeutic seclusion, either voluntary or involuntary, and pointed out the public approval of such treatment by Lord Aberdeen when Home Secretary, Earl Shaftesbury, Lord Selborne and Mr Justice Grantham, in addition to many eminent medical authorities.

DEATH DURING THE ADMINISTRATION OF CHLOROFORM

A boy, aged nine and a half years, suffering from necrosis of the lower jaw, was about to be operated on at King's College Hospital on the 3rd inst., but before he was brought under the influence of the anæsthetic he suddenly died. Chloroform was being administered in the usual manner on a towel, but after a few inspirations had been taken and whilst still quite conscious, the boy vomited, began to struggle violently, sat up on the operating couch with a markedly frightened aspect, and on being placed back, on the couch his spine became arched and his heart ceased to beat. The respiration continued for some minutes (at least five) after the cessation of the heart's action. Strychnin and ether were injected, ammonia was applied to the nose, hot and cold frictions, artificial respiration, tracheotomy and the galvanic battery were all in turn resorted to, but the heart gave no sign of renewed action. At the post mortem examination it was thought that there was a pale condition of the muscle of the right side of the heart and a somewhat thin wall, but nothing else abnormal was found. At the inquest, held on Wednesday, the jury returned a verdict of "Death from syncope through fright whilst under the influence of chloroform."

THE ETIOLOGY OF INFLUENZA

THERE is an interesting contribution on this subject in the March number of the *Zeitschrift für Hygiene* by Dr R Pfeiffer of the Institute for Infectious Diseases at Berlin. After describing the bacillus of influenza, the best methods of staining and the manner in which he overcame the difficulties, hitherto insurmountable, in cultivating this enemy of mankind, Dr Pfeiffer details the results of numerous investigations and points out the following practical deductions to be made from them. The bacillus grows very rapidly in pure cultures on a suitable soil, but no growth takes place at a temperature under 26° C (78.8° F) or over 43° C (109.4° F). In water at ordinary temperatures (60° F) the bacillus dies rapidly (in eight hours). In bouillon it retains its vitality for from fourteen to eighteen days. Hence sputum &c., if not allowed to dry, is probably infectious for at least fourteen days, and we may here find the explanation of cases, recorded by competent observers, in which the infection appears to have been communicated by means of letters, clothing &c. The bacillus is very rapidly affected by drying. Cultures exposed to dry air at a temperature of 37° C did not survive for more than two hours, and even in moist air usually not more than eight hours and never more than twenty. Sputum, if dried, was quite sterile in thirty-four to forty hours. Dr Pfeiffer draws the following conclusions from these facts—(1) The influenza bacillus is not capable of multiplication outside the human

as a component part of a teaching university, for which London is now well prepared. If adopted, having been emancipated from the fetters of the solitary school to which he is now restricted, the advanced student will find that his horizon is widened. "He will no longer learn *jurare in verba magistri*, but to form juster conceptions of science and to take hereafter broader views in practice than he possibly could when confined to the narrowing influences of the teaching of one set of men and the traditions of one hospital only, and he will be led to form a clear and considerate judgment of men whose opinions, though differing from those of his own teachers, he may yet find not to be entirely erroneous or undeserving of consideration." Of the separate Poor law infirmaries he formed a just and high estimate as storehouses of vast and varied sources of medical material for clinical purposes, but he hesitated to include them in his scheme of general professional education, lest it might be attended with some difficulties from the nature of their government. I believe that I am able in some degree to supply the missing link in his plan, partly from my personal knowledge of the character and organisation of those excellent and well managed institutions during the time I acted as the Local Government Inspector in London for Poor law purposes, whilst my friend Dr Bridges was employed in a Parliamentary inquiry into the working of the Factory Acts and in part from the evidence submitted to the Lords' Committee. The origin of these infirmaries was in a great measure due to the action of THE LANCET Commission of 1865 in exposing the defects of the Metropolitan Workhouse Infirmary system and to the public discussion to which its reports gave rise. This led to the passing of what is known as Gathorne Hardy's Act, the object of which was to remedy the defects of those infirmaries, which were acknowledged officially to be (1) insufficient medical care and nursing, (2) imperfect construction and sanitation, (3) overcrowding, and (4) deficient means of classification. Not only were these defects dealt with in the workhouses themselves to some extent, but the radical remedy of removing them altogether from all pauperising influences in their immediate control and arrangements has been eminently successful.

The testimony of the Lords' Commission on this point is to the following effect. Notwithstanding some objections in matters of detail which were offered in evidence, but did not touch the soundness of the principles underlying them, their lordships observed, "The evidence on the whole appears to indicate a general recognition of the high standard of efficiency attained by the best of the new infirmaries, both in their structure and in their general arrangements and management." There are now, according to Dr Bridges, twenty four of these infirmaries and forty four out-door dispensaries, in addition to the imbecile asylums and fever hospitals under the control of the Metropolitan Asylums Board. In the infirmaries are stated to be 12,445 beds, and in the other institutions referred to some 4700, according to a return in my possession. With two exceptions of the conversion of old buildings these infirmaries are all on the pavilion plan, and as respects ventilation, drainage and all internal arrangements necessary for the effective treatment and classification of the sick and injured are far superior to any of the general and endowed hospitals. There is a widespread impression that only chronic and some incurable diseases are contained in them but this is absolutely erroneous. There is no doubt a considerable proportion of chronic cases either transferred from the voluntary general hospitals or admitted directly, but there is also a very large number of acute cases of most of the ordinary affections prevailing amongst the poor. In fact the disorders of the classes which come under the operation of the Poor laws from infancy to old age and natural decay including every intermediate stage of life, with all the risks to which they are exposed in the busy periods of active life in London, can nowhere be studied with greater advantage than in the infirmaries referred to. In a decennial return furnished to the Local Government Board from one of these infirmaries there were 18,927 admissions of patients of whom 10,116 were recorded as cured, 2996 improved, 1078 took their discharge prior to cure, 690 were transferred to other institutions and 4047 died. None were ever sent away to provide beds for other patients and a very considerable portion of those who succumbed died from old age and natural decay—a class for whom no accommodation exists in general hospitals, rightly enough. In another return of deaths in one year in nineteen Poor law infirmaries 993, or 16.3 per cent., died from phthisis, 831, or 13.5 per cent., from chronic bronchitis, 571, or 9.5 per cent., from

chronic forms of paralysis, 451, or 7.3 per cent., from senile decay, 362, or 5.9 per cent., from chronic forms of heart disease, and 227, or 3.7 per cent., from kidney disease. In addition to the treatment of cases of acute and chronic disease, important surgical operations are performed in some, and might be in all, of these institutions with almost exceptional success, so that they are to all intents and purposes general hospitals in all but name, yet tainted most unfairly, I think, with the civil disabilities of pauperism from destitution.

With the sanction of the Local Government Board, I collected and published the statistics of 87,726 deliveries in Poor law infirmaries, of which 23,117 were in the metropolis, amongst whom the deaths were 0.88 per cent. out of the whole of the Poor law institutions within the registration area of London. In all the fever hospitals and imbecile asylums under the control of the Local Government Board records are kept which it would occupy too much space to reproduce, but the combination of all the conditions above mentioned shows what a vast amount of means of clinical instruction could be furnished by them, were they included in Mr Erichsen's federal scheme.

In addition to furnishing immediate medical relief to all cases provided with the requisite official authority, and to any very urgent case which presents itself even without such authority, the two most important considerations connected with the separate workhouse infirmaries, apart from their professional excellence, are the simplicity and efficiency of their management and the economy with which they are worked. The staff usually consists of a resident medical superintendent, with one or at most two qualified assistants, a matron, a steward, and a staff of nurses, who are mostly trained by themselves. The superintendent has undivided control over the whole establishment, and all hands are paid and resident and devote the whole of their time to their duties. This, I think, is the secret of their success, and accounts satisfactorily for the very large amount of work they are able to perform, with advantage to the sick and economy to the rate payers. I consider myself entitled to mention my own personal experience upon this question, for I at one time, in the early part of my career, occupied a similar position for some years, when I was the administrative and executive head of a general hospital, attached to a medical school, and containing 500 beds, as first physician and professor of medicine and clinical medicine. I had charge of one hundred of these beds, with a house physician to assist me. It gave me a considerable amount of purely professional work, and I had in addition the administrative charge of a medical school of some 200 or 300 students, a large number of whom were resident. All this I was enabled to get through simply because I was a paid resident responsible officer, and devoted the whole of my time to my duties. The college and hospital were governed by a Council of the Professors, of which I was a member, and all was again under the administrative control of a Council of Education, of which I was likewise a member and secretary. Neither of these bodies ever interfered with the details of management or in the individual personal responsible control of the whole institution, with every branch of which the college council was thoroughly acquainted. They acted as consultative bodies, and the latter carefully inspected the college and hospital at each of its meetings. The accounts and expenditure were audited by the audit department of the treasury. A somewhat similar government to this would be able to exercise a like efficient control over all our voluntary and endowed general hospitals, and more particularly those to which medical schools are attached, without additional cost, without a multitude of self elected committees between which there is no continuity of action, without unseemly contentions, and without overgrown establishments for which there can be no real need.

As to the introduction of clinical teaching in Poor law infirmaries and other institutions even in existing circumstances there would be no real difficulty if it is properly conducted and is not associated with any schemes introducing an outside element such as consultative honorary physicians and surgeons with a following of their pupils, who would not be under the control of the resident superintendent or of the boards of guardians who are responsible for the management of all the institutions in their several districts. The strong objections formerly entertained by all Poor law authorities including the Local Government Board, have nearly died out and are not likely to be revived, provided no proceeding calculated to interfere with their authority and

ment" in the year 1848. His age was seventy six and he died at Emmersdorf, where he had been living in retirement for some few years.

DR EDWARD MAUREL (*Mid. Medical*, Sept 10th and 17th, 1892) concludes from experiments that tuberculin, given in a therapeutic dose and in the usual manner, exerts no sensible action either on leucocytes or red blood corpuscles, and that, consequently, if tuberculin contains the product of the secretion and excretion of the bacilli of tuberculosis, the conclusion may be reached that such products have no apparent action on the formed elements of human blood. From further experiments he also thinks that the leucocytes of man offer an effective resistance to the bacillus tuberculosis, as numerous clinical facts show, and that it is sufficient slightly to attenuate the power of the bacillus (as he did by observing its action under various temperatures) to enable the leucocytes to triumph. These results, he maintains, would seem to justify the consoling thought that we merely require to discover an agent capable of bringing about this slight attenuation in order that we may be able to cure a disease which at present exacts a heavy tribute from humanity.

At the annual meeting of the Balneological Society Dr Kallay of Carlsbad, speaking of diabetes, distinguished two forms of the disease—the primary or genuine and the secondary or symptomatic. In the former the presence of sugar and symptoms bear a direct relation to one another and there is no organic disease. Appropriate diet and balneological treatment greatly benefits or cures such cases. In the second form symptoms are independent of the excretion of sugar and depend upon disease of some organ essential to life. Prognosis and treatment, therefore, in such cases depend upon the conditions of the primary malady.

THE London County Council have issued a series of regulations under the Glanders or Farcy Order of 1892 respecting the movement and marking of animals diseased with or suspected of glanders or farcy, and as to the removal of fodder, litter &c, the proper method of cleansing and disinfection in cases of such disease and the removal and destruction of the carcasses of animals so affected. The Council have also given notice that any person failing to intimate to the police that he has in his possession or under his charge an animal affected with glanders or farcy will be liable to a penalty of £20.

OUR remarks published in THE LANCET of March 18th with respect to the attitude of the Secretary for Scotland towards the question of county medical officers engaging in private practice have, we hear, been welcomed by our professional brethren engaged in that department of official work in Scotland. Amongst the appreciative notices of our conclusions on this point we have to acknowledge the thanks of the members of the Society of Medical Officers of Health for Scotland, conveyed to us by the hon. secretary of that Society.

At the next meeting of the Medical Society of London (April 10th) Dr W. R. Gowers, F.R.S., the Fothergillian metallist, will deliver an address on "Neurology and Therapeutics."

LITERARY INTELLIGENCE.—Messrs James Elliott and Co, Temple chambers, Falcon court, Fleet-street, E.C., are preparing for publication forthwith the whole of the alchemical and hermetic writings of Paracelsus, for the first time completely and faithfully translated into English, with the side lights of the chief commentators and exhaustive vocabularies and indices. The magnitude of the undertaking will necessitate its issue in the form of monthly volumes, the first of which is now passing through the press.

ON THE ORGANISATION OF MEDICAL RELIEF IN THE METROPOLIS

By F. J. MOUTAT, LL.D., M.D. EDIN., F.R.C.S. ENG.

IV

PROFESSOR ERICHSEN in his refined and opportune monograph on "hospital federation for clinical purposes" treats the question in a masterly manner, with a weight and authority which carry conviction, although he puts it forward in the modest garb of a suggestion. His eminence in his own branch of medicine, the commanding positions he has occupied, added to his personal and practical acquaintance with the educational needs of this vast metropolis during the whole of his professional life, invest him with unrivalled authority in all questions connected with the practice and teaching of hospitals. Hence no apology is needed for reproducing his views on this very important subject. He mentions that "in the report of the Royal Commission on a Teaching University in and for London it is stated that the opportunities for clinical instruction that exist in the Metropolis are unrivalled. That this is so admits of no doubt and that these unrivalled opportunities are not utilised to their full extent is equally certain." He proceeds to prove this from his personal knowledge and experience, and shows how injurious it is to the students of medicine at home, who are in consequence compelled to resort to foreign schools of repute to obtain information which exists at our own doors, and only requires to be properly utilised, to place the British school at the head of all others in Europe and America. Is it not possible, he says, to place London not only on a level with, but far in advance of, all other European capitals as a great school of clinical medicine and surgery in the widest sense of clinical teaching, as well as in its more special departments? He believes that by proper organisation of the enormous opportunities for clinical study that exist, but are dormant in London this may not only be accomplished but would place it in the pre-eminent position that it is entitled to, from the professional ability and excellence of its physicians and surgeons.

After specifying the number and nature of the charitable and other institutions within the metropolitan area devoted to the relief of sickness, he alluded to the separate Poor law infirmaries, of which he expressed a favourable opinion as possessing special merits of their own, and showed that without them the means of providing for sickness amongst the poor were numerically inadequate. He remarked that, as regarded the voluntary institutions, there was another potent factor in raising the standard of gravity for the in-patients of many of the London hospitals. It was their acknowledged insufficiency for all those who sought their aid. Hence a strict process of selection was adopted by the resident officers in the admission of patients, resulting in the admission of only the most severe, urgent and important cases.

The eleven largest general hospitals, with their 4542 beds, their special departments and maternities, he considered by far the most important, "not only on account of the number of beds they contain and the character of the cases that fill those beds, but of the acknowledged eminence, as practitioners and teachers, of the great body of physicians and surgeons attached to them." Taken collectively and federated together, so that the instruction given in them should be opened to the advanced students, they would constitute a great clinical school of medicine and surgery in all their branches, that would be without an equal in Europe. In this case union is strength. Taken collectively they are superior to all, but their weakness lies in their isolation. The remedy is to be found in the abandonment of the system of isolation that at present exists, and which neutralises the immense and undoubtedly unrivalled opportunities for clinical study that are to be found in the great hospitals and other medical charities of London. For this should be substituted a system of federation for clinical purposes. It is idle to talk of these opportunities as being unrivalled so long as the most important of them are cut up into as many distinct and separate fractions as there are hospital schools in the metropolis, and the remainder are scarcely, if at all, utilised. With a plethora of proof of the same practical character, Professor Erichsen formulated his plan of federation, which is simple, practicable and of moderate cost, and leaves untouched the autonomy of each institution embraced in its circle of action.

with portions of their capital to meet immediate wants, obtain grants in aid from some such source as a common fund, similar to that which exists in the Poor law practice of London, or in the Parliamentary grants of Dublin to enable them to fill their empty beds and to fund their legacies as means of permanent income, which would probably in a few years render them self supporting and independent of all esoteric aid! Upon this point the Duke of Devonshire, at a meeting held in Chesterfield in October last to raise funds for clearing off a debt on the local hospital, whilst intimating his preference for voluntary contributions when adequate, said "he noticed a great and increasing tendency to throw upon public resources, mainly upon the rates, the support of many institutions supposed to be of advantage and benefit to the whole community, and it did not appear to him at first sight very clear why no such proposal had been made concerning such useful institutions as hospitals. The expenses of public education, and in some places the expenses of free libraries and in providing public parks and other means of recreation for the people, were procured from public resources and it did not seem clear why such an institution as that hospital should not be supported from the same source." The main contention of this prominent and influential statesman is, I think, correct, and private charities must perforce bear a fair share of the influence of the rapid advances in economic doctrine and practice in the matter of individual as opposed to collective questions and public control. Collectivism is said to be the leading economic fact of our time. I am by no means sure that the best intentioned example of this collectivism in relation to hospitals—the Hospital Sunday Fund—has not proved a two-edged weapon, and has not diminished rather than increased the contributions of the general public towards the maintenance of these institutions. It has also injured its position in assuming a commanding influence and officious inquisition into the affairs of the hospitals amongst which its funds are distributed by a standard of its own, which does not, and cannot take note of the real value of hospital work in its technical and professional aspects. This is evident in the feeling exhibited at the meeting recently convened to prepare a working scheme of a central hospital board for London.

It appears to me that it would answer no useful purpose in existing circumstances to examine the other more or less subsidiary matters and conclusions contained in the Lords' report. They are, for the most part, details of administration of which there is need for more exact information than is contained in the evidence for them to be dealt with authoritatively, in addition to which they legitimately admit of diversity of management without any sacrifice of principle. To change or modify them would necessarily be a work of time, and no good would be done by attempting to force upon unwilling authorities measures which do not secure their support and concurrence. The most important of them is the relation of the schools to the hospitals, a question which will enter into entirely new conditions with the establishment of a Teaching University for London, which is probably near at hand. On the question of nurses I had rather not enter. Prolonged as the inquiry was in this matter, no fresh light was thrown upon the training, diet, discipline and duties of the valuable body of hospital helps, and the general treatment of the matter was so far beneath the dignity and purposes of the committee as to be a subject of grave regret. A sensible and practical working solution of the introduction of a uniform system of hospital accounts was framed, and a similar record of hospital statistics in their scientific aspects will not be difficult to discover when the time arrives for its general authoritative introduction.

The remaining link in the chain of my contention is the grouping of the hospitals and other institutions devoted to the care and treatment of the sick poor of London, which will need for its understanding a map of hospital London brought up to date. This I hope to be able to supply.

MR. HORACE LOWTHER of Ventnor has been awarded the grant (fourth time) for efficient vaccination in his district.

MR. T. ANDROS DE LA RUE, the chairman of the Royal Hospital for Diseases of the Chest, City road, E.C., has sent in connexion with the forthcoming festival dinner a donation of 300 guineas and Messrs. Thomas De la Rue and Co., of Bunhill row, have promised 100 guineas.

CHOLERA.

CURRENT NOTES, COMMENTS AND CRITICISM.

FROM the accounts that have been received from Russia, Austria and France there cannot, we fear, be any doubt as to cholera having reappeared with the commencement of this spring, in obedience to those seasonal influences which tend to call forth, revitalise and develop it into activity. Cholera, all the world over, comports itself in much the same way, and its epidemic manifestations occur in obedience to some natural laws which cannot fail to be recognised eventually, notwithstanding that we have as yet been unable to fathom all the factors and reduce them to any scientific formula. There would be no need otherwise to have recourse to figurative language in our descriptions of its epidemic progression. A recrudescence of the disease—in the shape of localised outbreaks and sporadic cases at different places—during this season is the frequent precursor of its epidemic prevalence later on. From Russia we learn that it has broken out in the St. Petersburg district and in the Western Provinces. It is said to be raging in Russian Podolia, whence, according to reports from Vienna, it has been introduced into two villages in Galicia—at Zalucze and Kudrynce on the Russian frontier—by individuals who have lately been in Podolia. Both villages have been isolated to prevent the inhabitants from carrying it elsewhere. A later telegram from Vienna states that cholera has been imported from Russia into another Austrian frontier village and caused 5 cases and 2 deaths. Fears are very naturally entertained that the epidemic in the interior of Russia will manifest itself with renewed intensity when the warm weather sets in. In view of the recrudescence of the disease the Zemstvos are organising a special sanitary corps, consisting of doctors, hospital attendants and nursing sisters for active service, if necessary in the threatened provinces and meetings of medical officers are being held in these provinces to devise precautionary and other measures with the same object in view.

According to the latest official returns from St. Petersburg 65 cases of cholera and 19 deaths occurred in the town of Orel during the week ending March 26th. In the province of Oufa there were, from March 12th to 27th, 84 cases and 29 deaths, whilst in that of Elizabetopol 10 cases and 4 deaths occurred between March 22nd and 29th. The cases and deaths in other provinces not mentioned in the official returns are far more numerous, especially in Podolia and Saratoff.

We learn also from *The Times* that the anticipations of the reappearance of cholera in western Europe this spring are being realised. At Lorient, on the French coast, between Brest and Nantes, it has caused nearly 70 deaths in the course of the last fortnight and the epidemic is still extending. The type of the disease in France is stated to have been milder than in Russia and Germany, but it is estimated that there have been about 200 cases of cholera in Lorient during the last two weeks. The population of Lorient is about 40,000 and the sanitary condition of the town, as regards water supply, drainage and cleanliness, is not worse than that of many other provincial towns in France, is nevertheless most unsatisfactory and the conditions under which the bulk of the population live are favourable, instead of inimical, to the development of any epidemic disease. That this is so is evident from the medical history of the town in connexion with the prevalence of typhoid fever. Lorient is a naval arsenal. The naval forces quartered there during the six years ending 1890 amounting to an average strength of 4000 lost nearly 300 men from typhoid fever and the small military garrison have also repeatedly suffered from the same disease.

In connexion with the fostering influence of insanitary conditions and their intimate association with the prevalence of epidemic disease, it is a noteworthy fact that a serious outbreak of typhus fever is stated to have broken out in the vagrants' wards of the Nanterre prison, where it will be remembered, a very severe and fatal outbreak of cholera occurred last year. The disease was traced to individuals who had come from the police dépôt at Paris, but the past medical history of the Nanterre institution shows that there must be something radically wrong with the sanitary condition of that institution.

their public responsibilities be introduced. From my personal knowledge of boards of guardians in all parts of England and Wales and of the institutions under their control and management, I am satisfied that they are actuated generally by the best intentions in the fulfilment of their very important and somewhat unpopular duties, and I found them always disposed to adopt any measures of improvement of the desirability or necessity of which they were satisfied. The institutions themselves are, in many cases, misunderstood, for I have seen much happiness and contentment, particularly amongst the old people, with the kindness and consideration with which they were treated. To regard them as bogies and bugbears appears to me to be as impolitic, as it is unsound in principle. It will never reclaim the really vicious, ill disposed and incorrigibly idle, it has, I fear and believe, little or no influence on the cultivation of thrift, and is certainly disregarded by the majority of the proletariat in resorting to the Poor law infirmaries when seriously ill. The stigma of pauperism has no real significance for the professional tramp or incorrigible idler and criminal, but would often act injuriously upon those whose destitution is not due to any vices or acts of their own, but to sheer misfortune and ill success in life, for whom the provision of a quiet retreat is provided by one of the most beneficent Parliamentary measures ever passed—the Poor Law Act of 1824. The extension of the provisions of the Medical Relief Disqualification Removal Act of 1885 to the Poor law infirmaries (which, by a legal fiction, are constructively parts of a workhouse) would not only be just to the great class of well conducted artisans and labourers, whose temporary poverty is due to sickness and physical disability alone, and would be a positive gain to the voluntary hospitals, enabling them at once to sift their claimants to admission, and to reject those who are unable to bring proofs of their identity. It would also solve another problem of extreme difficulty, such as the unequal distribution of the voluntary hospitals of London owing to the great shifting of population, thus concentrating them where they are not much needed, and leaving great bodies, particularly of the poor, far removed from hospital aid. To transplant any of the older institutions from their present positions, even if it were practicable, would cause an expenditure for which neither the State, the municipalities, nor private benevolence are in any way disposed or prepared. It, moreover, does not necessitate any expenditure whatever, for a well ordered Poor law infirmary is situated in each of the Poor law districts, and these infirmaries would, as general hospitals for the poor only, with the existing voluntary institutions for the classes immediately above them, be ample for all the hospital wants of London. Their lordships expressed a great desire for a map to guide them in the matter, and were unable to find one. I am unable to understand how this happened, for I placed in the hands of one of them the best map yet constructed, which indicated the exact position of every hospital, Poor law infirmary, lunatic asylum, and Poor law dispensary within the metropolitan area. I suppose he must have overlooked it.

Now that the successful character and efficiency of the Poor law infirmaries are fully established, by a system of affiliation or federation such as Professor Erichsen suggests, all the hospitals could assist each other materially with much advantage and no detriment to any of them, as well as without the sacrifice of any of the principles associated with the proper bestowal of charity, either public or private. There need be no more emptying of beds for any illegitimate purpose, the sick poor who are unable to pay anything for treatment would be able to find immediate admission in all cases requiring it, without any danger of aggravating their sickness by waiting for vacant beds or subscribers' letters, and in all cases taken in their earliest stages would have the best possible chances of recovery and speedy return to their work. If the records and statistics of these institutions were carefully kept on a uniform plan, a flood of light would be thrown upon the value of the work done from the professional standpoint, and upon the management of all affections requiring prolonged treatment, such as cannot be now afforded by the voluntary hospitals. The federation of the hospitals, again, if properly directed and carried out, would materially affect the cost of maintenance, which now fluctuates to an extraordinary and unexplained extent—according to Mr Burdett from £100 to £30 per bed occupied. Combined action would lead to economy, as seen in the working of the central system of Paris. An official inquiry made into such a plan for the workhouses and pauper schools of the metropolis, the latter of

which I conducted, showed how valuable such a proceeding would be, but it was not adopted by the different boards of guardians, who would not then voluntarily combine for any purpose whatever.

In the matter of nurses, the Poor law infirmaries have shown that they can train them for their own use as well as any of the older institutions which make a traffic of their services for their own advantage, which is a doubtful means of adding to their resources. In the former the matrons, all classes of nurses, and establishment generally, are under the sole control of the superintending medical officer, in consequence of which undivided authority there is a total absence of friction.

With reference to the general introduction of clinical teaching in the Poor law hospitals, it will have to be carried into effect with extreme care and caution. The existing procedure cannot, I think, be adopted with any chance of success so long as attendance for clinical instruction has no acknowledged place and value in examinations as a necessary qualification for the higher offices of clinical clerks and dressers, and the most coveted positions of house physicians and surgeons, which frequently end in the highest prizes of the practising profession—the medical and surgical staffs of the great hospitals. In these positions, the best men will always come to the front, and acquire the fame and fortunes which are the well earned accompaniments of an eminence fully equal to that of every other branch of human intelligence and action, although it has not yet led to such social distinctions as are lavishly bestowed upon the Church, the Bar, and the Army and Navy.

The advantages, then, of converting the present Poor law infirmaries into general hospitals without civil disabilities appear to me greatly to outweigh any objections of principle which can be brought against the proceeding. That State aid can further demoralise or pauperise those who only claim it in times of acute suffering and are entitled to it I cannot understand. That it will discourage or prevent the practice of thrift is still more incomprehensible, as those who have nothing to save cannot in any circumstances put any thing by for a rainy day, since "Ex nihilo nihil fit." That it will dry up the existing sources of private charity I do not believe, that such help in sickness should only be given to the deserving poor may be correct in principle, if practicable, but sickness is an inexorable enemy which cannot be vanquished by any speculative measures. It demands immediate aid, however undeserving on moral grounds the recipients may be. Poverty is not a crime and should not be treated as if it were, and the working of the Poor laws should be acts of beneficence and not of oppression, even in those of its provisions which are necessarily restrictive of personal liberty of action, in the maintenance of order and discipline.

The present practice of the voluntary hospitals militates against the true principles of charity far more than aid in the Poor law infirmaries would, even if all civil disabilities were removed, for I do not consider the giving of relief, either to out-door or in-door patients, without the production of proper means of identification, to be at all satisfactorily met by any of the processes heretofore adopted. The conversion of the Poor law infirmaries would not increase, but, if properly carried out, ought to diminish, the pressure upon the rates, and it would not in any way touch the collection or distribution of the Hospital Sunday or Saturday funds. It would entirely stop all such objectionable proceedings as compelling patients to supply their own tea, sugar, or any other articles of personal comfort, and would never sanction the emptying of beds in unrelieved cases, with regard to which I entirely share the views of all foreign observers who have denounced the practice.

The accommodation available for the wants of London in dealing with sickness associated with poverty is certainly insufficient in existing circumstances, and empty beds, whatever their number may be, ought not to exist so long as they are required. Is there no remedy for this? I think there is, and although the suggestion for its amendment may meet now with a chorus of disapproval, it will, I believe, become inevitable in the near future. The present state of public feeling on the subject of the Poor laws and the wisdom of extending State intervention is decidedly favourable for regulating individual or even collective action where it is more required, as in the case of hospitals, than it was in factories, mines, and other economic undertakings in which it has proved eminently successful. Why, then, should not voluntary hospitals, which are almost all living beyond their available resources and parting

March 1st, 1883, states that, including some suburban districts, there are 32,653 houses in Marseilles, of which 5000 employ *tinettes filtrantes*, 4000 have *pousards*, 10,000 the dry pail or the *tinettes seches*, and 13,600 houses have no appliance of any kind, and must of necessity throw every thing into the street.

There are some houses, however, which possess private drains. During the last fifty years plumbers, when erecting closets in houses built in streets where there were no sewers, sometimes laid small earthenware drains in the street to carry away the slop-water, the overflow from the *pousards* or the *tinettes*, to the nearest sewer. These private drains were laid down without any sort of control or general plan. The greater their number the greater the profits of the builders and plumbers. Thus, in some streets there are as many as five private drains running side by side to the same sewer. Most of these drains are badly built and badly kept. Some are blocked up, others have burst, some do not even reach a sewer, and in many cases the record of their existence has been lost. No wonder that the subsoil of Marseilles is thoroughly contaminated. By far the greater part of what should constitute the sewage of Marseilles travels over the surface of the streets, along gutters that are not cemented, and has therefore, every facility of sinking into the earth. Yet in this earth, so constantly and widely contaminated, there are wells, and many people prefer the water of these wells because it is cool in summer time. The consequences are often fatal. For instance, some years ago there existed in the Rue Montgrand a boarding house where some thirty young men daily took their meals. Within one month seven of these boarders were taken ill and five died. The symptoms were most violent and similar in each case. There was a well in this house and leaking cesspools around. The first cases of cholera in 1885 occurred in a house where well water was drunk. It was also noticed that a case of cholera having occurred in the commencement of the Cours Lientaud, the cholera broke out successively in the Rue Neuve, the Rue Chateau Redon, the Rue de l'Académie, the Rue du Musée and the Rue Lorgue des Capucins. In that particular district the disease travelled downwards with the water from street to street, as if the cholera dejecta thrown out in the street on the higher level had infected the people living below.

From all these facts it will be seen that the condition of the domestic drainage is so deplorable as to suffice by itself to account for the high death rate and the numerous epidemics that afflict Marseilles. This, however, is not all. There remains still much to be said concerning the defective state of the public sewers and water supply.

OUTBREAK AT LORIENT

We hear that, upon the receipt at Whitehall of the news that cholera had broken out severely at Lorient, on the French coast between Brest and Nantes the Local Government Board immediately communicated with all the port and riparian sanitary authorities throughout the country, informing them of the fact. The news of this outbreak is indeed serious, and we sincerely trust that the sanitary authorities will heartily coöperate with the Local Government Board in the energetic steps they are taking to place our defences in proper order. It is true that the trade between Lorient and this country is not large, but there is obviously great danger of the disease shortly spreading to those French ports along the Channel, such as Havre, St. Malo, Cherbourg &c., with which we have frequent communication. The Channel Islands, too, are not unlikely to act as a stepping stone for cholera between France and this country, and in this connexion it is gratifying to learn that Dr Theodore Thomson is at the present time conferring with the authorities of these islands in reference to the precautions it is desirable for them to take. Lorient has, it appears, a heavy death rate from enteric fever, and this fact should prove an ominous warning to those districts in our own country which have a high mortality from the same disease.

A CANCER HOSPITAL FOR VIENNA.—Information has been received that Baron Albert Rothschild has given half a million florins for the purpose of founding a hospital for the treatment of persons suffering from cancer. It is understood that the gift is intended to commemorate the death of the late Baroness, who, it will be remembered, died from cancer.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT

REPORTS OF MEDICAL OFFICERS OF HEALTH

Parish of Chelsea.—The estimated population of this parish in the middle of 1892 was 97,341. The general death rate amounted to 20.8 per 1000, influenza having caused as many as 84 deaths. The zymotic death rate was a high one, being 3.1 per 1000, as against 2.8 for London generally. This excess was in a large part due to the epidemic prevalence of measles no less than 106 deaths having been attributed to it. Dr Parkes, assuming what is probably the case, that influenza is chiefly responsible for the excess of death rate from respiratory diseases over the average of non epidemic years calculates roughly that there have been sacrificed to this disease during 1892 some 140 lives in Chelsea and about 4200 in London. The quality of the water supply to Chelsea during the past year is said by Dr Parkes to have exhibited a considerable improvement on the supply during 1891. We read that in November, at a time when the Thames water was brown and turbid, the Chelsea Company succeeded in removing by filtration 47 per cent. of the organic matter and no less than 99.8 per cent. of the micro-organisms, which can grow on gelatine plates at the ordinary temperature of the atmosphere. It would be interesting to learn what proportion of those capable of growing at the body temperature could be removed by the filter beds referred to. In discussing the subject of filtration Dr Parkes calls attention to the immense importance of maintaining its efficiency during the present year, as upon that, he states, may depend the immunity of London from Asiatic cholera. It would be instructive if some research could be undertaken to show the behaviour of the comma bacillus in water which had passed through the filter beds of the several water companies of London. As Dr Parkes points out, experience has shown that cases of cholera can, and do, elude the vigilance of the port sanitary authorities. This is of course a fact which is fully recognised by the Local Government Board, and hence their praiseworthy efforts to stimulate riparian and other sanitary authorities to put their districts in order whilst the opportunity exists. Treating of the housing of the working classes, Dr Parkes expresses his opinion that a clause is wanted in the Housing of the Working Classes Act, 1891, prohibiting an owner from letting or permitting to be occupied, any part of a house for which a magistrate has issued a closing order.

Liverpool Port Sanitary Authority.—Dr Stopford Taylor opens his report by reminding us that in 1866 cholera was introduced into Liverpool by emigrants coming from Germany and that it then caused no less than 1782 deaths. The report tells us that during the prevalence of cholera at Hamburg last year two additional medical officers were appointed to inspect all ships coming from cholera infected ports. The total number of vessels entering the port during 1892 was 21,687. Of these 5167 were engaged in the foreign trade and 16,520 in the coastwise. Out of this total some 3867 were inspected. Of these 3399 were found in "fair condition" and 468 defective, in 174 cleansing operations were ordered, in 25 the bulkheads were faulty, in 165 there were damaged and useless ventilators, in 66 the closets were out of order, in 38 the decks required caulking. The number of emigrants passing through Liverpool during 1892 was 5632 less than in 1891. The reduction is more than accounted for by the great falling off of passengers to the United States during the cholera scare. It is instructive to read that during the months of August and September the clothing of all transigrants was fumigated under the supervision of an officer from the United States Consulate, prior to their departure for America. If the fumigation was carried out with sulphurous acid gas the United States has apparently much greater faith in the penetrative power of this gas than we have. Altogether there were fifty six ships reported during the year 1892 as either having or having had zymotic disease on board, and Dr Stopford Taylor gives a short account of the measures adopted in each case. We read of several vessels having been disinfected by the crew but the report does not state how this was effected. In view of Dr Stopford Taylor's great experience it would have been very acceptable had he given us a short account of the process by which disinfection of vessels is carried out in his port.

As regards this country we may here advert briefly to the important report which was submitted last month to the Court of Common Council by the Port Sanitary Committee and Dr W Collingridge, the medical officer of the Port of London, and adopted by the Court. Her Majesty's Customs have for many years acted as the quarantine authority and have worked conjointly with the port sanitary officers, and it has now been proposed that the two shall be divided and work independently. But Dr Collingridge pointed out that this would be attended with additional expense and other difficulties, and recommended the continuance of the present system for this year at any rate. He dwelt upon the importance of avoiding any unnecessary detention of vessels and unjustifiable interference with trade, and on the importance of Gravesend, supplemented by other points on the river if necessary, and the use of the telegraph as to the approach of suspected vessels. Dr Collingridge also proposed the establishment of a small floating hospital, and recommended that £2000 should for the present be placed at disposal for making provision in the port for the transport and isolation of cholera cases &c if found necessary hereafter.

A notice has since been issued by Sir John Monckton, Town Clerk of the City of London, stating that in consequence of a recent decision of the Commissioners of Customs a separate boarding, for the purpose of the medical inspection of vessels coming into the port of London from the various places abroad which are enumerated, will be made on and after April 1st by the medical officer of the Port of London Sanitary Authority, independently of that made by the officers of Customs. Arrangements have been made to place a hulk off the Port Sanitary Hospital at Denton, below Gravesend, from which the separate boarding and medical inspection of vessels will be made in a steam launch. Every vessel arriving from any of the specified ports and places will be brought up at the above point until inspected by the medical officer of health of the port.

The Medical Department of the Local Government Board appear to be fully alive to the possible gravity of the situation, for they have already taken, or are taking, steps to inform the Port Sanitary authorities throughout the country of the fact that cholera has again broken out on the Continent. Her Majesty's consul at Brest has informed the Foreign Office of the occurrences that have taken place at Lorient on the north western coast of France, to which we have already referred. Dr Thorne Thorne, the medical head of the Local Government Board, is still at Dresden attending the International Conference upon cholera, and is not expected to return to his duties in England for the next three weeks.

CHOLERA IN FRANCE

(FROM OUR SPECIAL CORRESPONDENT.)

A VISIT TO MARSEILLES—II

Futile Litigation—Bread making over Open Drains—An Objectionable Pail System—Contaminated Wells

It need scarcely be said that from time to time the municipality of Marseilles has sought to amend its drainage, not merely by discussing general schemes, but by improving the contrivances in actual use. The latter efforts, though leading to much litigation, have been of little practical service. So far back as Feb 17th, 1859, a municipal by law or decree was published forbidding the draining of night soil into the streets, gutters or sewers, yet to this day, as I have already described, there are very few cesspools in Marseilles, and the inhabitants of some 14 000 houses throw their soil into the streets. In 1865 the municipality awoke to the fact that the small cesspits under the causeways in front of the better class houses were an abomination. They said that these cesspits were only meant to be used as grease-traps, inasmuch as they were intended to receive only rain water and kitchen water—in fact, instead of being small cesspools they were only clumsy and large gullies. But the tribunal, in its verdict, declared that the administration had remained silent for twenty five years, that the *puisards* had been constructed according to the plan drawn up by the municipality, that similar *puisards* existed in front of buildings belonging to the municipality itself, that, though it was illegal to drain fecal matter into the sewers, the *puisards* had gratings which permitted only the liquid overflow to reach

the sewers, and that, therefore, under these circumstances, the persons prosecuted for draining their closets into their *puisards* must be acquitted. Against this verdict appeal was made, and the municipality even succeeded in causing some persons to be fined, but only one franc each, for the condition in which their *puisards* were found. Whatever may be the law is not very easily ascertained, and this in the face of the many trials and the contradictory verdicts obtained, and the fact remains that the *puisards* are still nothing but small cesspools with overflow pipes to the sewers. The Municipal Commission appointed in 1886 to investigate this matter—after visiting the *puisards* in some of the best streets of Marseilles, notably the Rue Saint Ferreol, where foreign visitors do most of their shopping—reported that “In the greater number of *puisards* the masonry seemed rough, uncemented and likely to allow a large quantity of liquid to filter through into the surrounding earth. Many were devoid of water. Excremental matter had accumulated at the bottom and was in a state of fermentation, and the gaseous products infected both the sewer and the houses. The houses were also exposed to the gases from the sewer as well as those generated in the *puisards*.” This state of things still prevails.

With regard to the *tinettes filtrantes*—that is, the pails, which allow the liquids to escape into the street gutters—the municipality decided that these should be permitted only in houses which had subscribed to the town water supply. Of course where there is a great quantity of water used the liquid escaping from the *tinettes* is less foul, but it is probable that, in its practical results, this measure has done far more harm than good. It has helped to disguise rather than to prevent the evil. If there is not much water thrown into the *tinettes* the nuisance caused by the overflow would be more offensive and the necessity of employing some other method of drainage would be rendered more evident. On the other hand, the danger is none the less. Cholera dejecta are thrown into a closet and fall down the soil pipe into a metallic pail. All the water thrown into the closet filters through these dejecta, and passes along the hall of the house into the street gutter. A part sinks into the earth between the paving stones of the gutter, but the rest finds its way to a distant sewer and then into the port. What must be the condition of Marseilles during an epidemic with the water that has filtered through the solid deposits of some 5000 soil pails flowing down the street gutters? In one house thus drained, and which I visited, I found on one side of the passage that an indenture only had been made in the stone flooring. The pail was under the staircase at the other end of the passage, and along this indenture flowed the befouled liquid which escaped from the pail. On the other side of the passage, within a yard of this open drain and with open doors facing it, there were men actually at work making bread. In another house the tap supplying the drinking water was placed immediately over the open drain. Thus, to fill a jug with drinking water, the jug had to be placed over an open drain within an inch or so of the fecal matter which, in solution, escaped from the *tinette filtre*, or pail. These *tinettes filtrantes* are, I have already observed, only used where there is a good deal of water consumed in the house, otherwise the water overflow would be abominably offensive, and this, I cannot help thinking, would be an advantage, for persons would then hesitate to draw water and make bread in such close proximity to open drains, they might even go so far as to demand a better system of drainage.

In houses where there is no water supply the *tinettes filtrantes* are not allowed to be used and the *tinettes seches* or dry pails are enforced. As already mentioned, the inhabitants have no closet in the house, but have to carry down and empty their utensils into the dry pail. The scavengers are supposed to remove these pails periodically. In practice, if the dry pail is used a great nuisance is created. The pail has no lid and is therefore very offensive. The mouth of the pail is small, consequently soil is constantly spilt outside the pail and infects the cupboard or niche where it is kept. The result is that tenants and others are generally urged not to make any use whatever of the pail. It is kept on the premises to satisfy legal exigencies, but not for use. I visited several houses of this description and found the pails perfectly dry, there was nothing in them. The inhabitants had simply poured everything out into the gutter in front of their houses. There are about 10,000 houses in Marseilles which have dry pails. An official report, bearing the date of

THE SERVICES

MOVEMENTS IN THE MEDICAL STAFF

SURGEON MAJOR R. W. FORD has been taken on the strength of the southern district. Surgeon Captain W. G. Clements has been taken on the strength of the Chatham district and posted to Chatham for duty. Surgeon Captain F. W. G. Hall has joined at Woolwich for duty. Surgeon Captain F. T. Skerrett has arrived home from India. Surgeon Major A. A. Lyle has proceeded to Strensall from York and assumed charge of the Station Hospital and camp vice Surgeon Lieutenant G. J. Buchanan. Surgeon Major Sharpe has been posted to Ireland for duty, and Surgeon Captain Cardew to the south eastern district. Surgeon Lieutenant Thurton, lately attached to the Coldstream Guards, has been posted to the southern district for general duty. Surgeon Captain Long has arrived at Sierra Leone. Brigade Surgeon Lieutenant-Colonel Carew and Surgeon Captains Melville and Wilson have arrived in the *Crocodile* on completion of a tour of service in India. Brigade Surgeon Lieutenant-Colonel Taylor has arrived from India on appointment to the Headquarters Staff at the War Office. Brigade Surgeon Lieutenant Colonel Caffie has been ordered to Belfast. Brigade Surgeon-Lieutenant Colonel Nash will succeed Surgeon Colonel Jameson as Principal Medical Officer of the army of occupation in Egypt. Surgeon Major Franklin has embarked for Gibraltar. Surgeon Captain Walker has joined in Dublin for duty. Surgeon Captain Weston has been transferred to the southern district.

Surgeon Lieutenant-Colonel H. H. Stokes having reported his arrival at Netley is posted to the Surgical Division of the Hospital. H.M.S. *Serapis* is expected to arrive at Netley about the 6th inst. with 219 men, 6 women and 10 children for Netley.

The Medical Establishment in Egypt has been augmented by three medical officers and two nursing sisters and a detachment of the Medical Staff Corps.

ARMY MEDICAL STAFF

The undermentioned Surgeon Captains retire from the Service receiving gratuities (dated April 5th, 1893).—Wm. Henry Phillips Lewis and Frederic William Reid, M.B. Surgeon Captain John Francis Bateson, M.B., is seconded for service with the Egyptian Army (dated March 16th, 1893). Surgeon Major General J. B. C. Reade, Professional Assistant to the Director General of the Army Medical Department, having completed the period for which he was granted an extension, will consequently be placed on retired pay. Brigade Surgeon Lieutenant-Colonel R. N. Macpherson attains on the 9th inst. the age of fifty five and will therefore be placed on retired pay from that date.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon Captain Thos. Fort, 6th Volunteer Battalion, the Manchester Regiment, to be Surgeon Major (dated April 5th, 1893). Surgeon Captain William Kinnear, M.B., 3rd (Dundee Highland) Volunteer Battalion, the Black Watch (Royal Highlanders), to be Surgeon Captain (dated April 5th, 1893).

INDIA AND THE INDIAN MEDICAL SERVICES.

The following appointments are announced.—Surgeon Lieutenant-Colonel R. Exham, Army Medical Staff, to be Secretary to the Principal Medical Officer, H.M.'s Forces in India, *sub pro tem*, vice Brigade Surgeon Lieutenant-Colonel W. Taylor, M.D., Army Medical Staff, who has been summoned to England for duty in the office of the Director General, Army Medical Department. Surgeon Major D. Finch Mullen, M.D. Indian Medical Service (Bengal), Residency Surgeon in Meywar, to be Civil Surgeon of Ajmere and Medical Officer of the Merwara Battalion. Surgeon Major P. D. Pank, Indian Medical Service (Bengal), Civil Surgeon of Bikanir, to be Residency Surgeon in Meywar. Surgeon Captain R. Shore, M.D., Indian Medical Service (Bengal), to be Medical Officer of the Meywar Bhil Corps. Surgeon Captain Shore will continue to officiate as Medical Officer of the Deoli Irregular Force and of the Harowtee and Tonk Political Agency. Surgeon Captain J. G. Jordan, Officiating Civil Surgeon of Noakhali, to act as Civil Surgeon of Backergunge until further orders. Surgeon Major A. E. R. Stephens, Officiating Civil Surgeon of Puri, to be Civil Surgeon of Jessore. Surgeon Lieutenant W. E. A. Armstrong, 1st Regiment Madras Infantry (Pioneers) Indian Medical Service, to the officiating Medical Charge of the

Regiment. Surgeon Captain J. K. Kanga, 17th Regiment Madras Infantry, Indian Medical Service, to the Officiating Medical Charge of the Regiment. Surgeon Captain W. G. Pridmore, 21st Regiment Madras Infantry (Pioneers), Indian Medical Service, to the Officiating Medical Charge of the Regiment. Surgeon Captain W. H. Bean, in medical charge, Station Hospital, Cannanore, is posted to do duty, Madras district. The services of Surgeon Captain T. C. Moore, Indian Medical Service, are placed temporarily at the disposal of the Public Department. Surgeon Major E. F. H. Dobson, M.B., Civil Surgeon, Goalpara, is transferred to the Khasi and Jaintia Hills district. Surgeon Captain J. C. Lamont, Indian Medical Service, Bengal Establishment, whose services have been placed temporarily at the disposal of the Chief Commissioner of Assam, is appointed, until further orders, to be Civil Surgeon of the Goalpara district from date of taking over charge from Surgeon Major E. F. H. Dobson, M.B. Surgeon Captain H. Handley, Civil Surgeon, Peshwar, has obtained furlough to Europe for one year from April 12th, 1893. Brigade Surgeon Lieutenant-Colonel W. H. Climo, Army Medical Staff, has obtained leave for six months on medical certificate, and Surgeon Captain F. W. Reid, on private affairs from date of availing himself of it, pending retirement.

NAVAL MEDICAL SERVICE

The following appointments are announced.—Surgeons—William E. Home to the *Shallow* when re-commissioned (undated) and Frederick A. Brice to the Cape of Good Hope Hospital (dated March 29th, 1893).

THE VOLUNTEERS AT NETLEY

Surgeon Lieutenant-Colonel Norton and officers of the Volunteer Medical Staff Corps were entertained at dinner on Monday, the 3rd inst., by Surgeon Major General Broke Smith and the officers of the Medical Staff. Drills took place after 2 P.M. for Volunteers. An officer of Volunteers was detailed daily as supernumerary to the orderly officer, Army Medical Staff, and was on duty for twenty four hours. Half the company of Volunteers were detailed for work in the medical and half in the surgical division of the hospital. The company attended divine service on April 2nd at the hospital chapel. On Monday a grand field day took place with the Hampshire Yeomanry.

PHYSICAL EXAMINATION OF CANDIDATES FOR THE ROYAL MILITARY ACADEMY

It is announced in *The Times* of the 6th inst. that hence forth only the successful candidates for admission to the Royal Military Academy will be inspected by a medical board and no candidate will be considered eligible unless certified by the board to be in all respects physically fit for Her Majesty's service. No candidate will be admitted to the Academy unless certified by the medical board to be in all respects, as to height and chest measurement, fit for Her Majesty's service, except where the board, having regard to the candidate's age and physique, expressly state that they are of opinion that there is every reasonable probability of his fulfilling the requirements of the service in the particulars referred to at the time of his completing his course of instruction and qualifying for a commission. The admission of such candidate to the Royal Military Academy will only be allowed on the understanding that he will not be granted a commission if he fails to attain the physical standard which may be in force at the time of the entrance examination. The present minimum standard for officers is 5 ft. 4 in. height and 33 in. chest measurement. The medical inspection will be held at the following stations: Colchester, Devonport, Dover, Edinburgh, London, Portsmouth, York, Belfast, Cork and Dublin. Candidates will be allowed to select the stations at which they wish to be medically examined. The decision of the board will in all cases be absolutely final.

THE BULLET PROOF FABRIC

This subject is still attracting a good deal of attention in Germany and on the Continent. We strongly suspect, however, that it will be a long time before soldiers go to war as a sort of pastime, owing to the battle-field having been robbed of its dangers by the resistance of the fabrics worn by them to rifle and revolver bullets. Even if the bullets do not penetrate these textures there is the effect of the force of impact to be considered, and we have not yet experimentally ascertained what this will be on living animals encased in a sort of wire netting covering. As it was very unlikely that Herr Dowe, or anyone else, would act upon Professor Billroth's humorous remark, that it would have been

Kingston on Thames Rural Sanitary District—This report contains a good map of the district to which it refers, and, although it is but a small matter, we must confess that a map, such as this, enables a report to be followed very easily. The district in question had during 1892 a general death-rate of 16.24, a zymotic death rate of 1.48 and an infantile mortality of 130.4 per 1000 births. Out of 14 samples of water analysed during the year no less than 11 were "largely polluted with sewage" and 2 were "unsatisfactory." It is gratifying to note that the antagonism of the working classes to having their children removed to the isolation hospital is dying out. There were 29 cases of diphtheria in the district during the year and 12 proved fatal. Dr Gibbs records that he saw several cases of sore-throat in Weston green, and, although it was impossible to classify them as diphtheria, they were clearly of an infective type. The patients were therefore ordered to be isolated and thus, in Dr Gibbs' opinion, an outbreak of diphtheria was avoided. We certainly think that the right course was adopted in this case. Dr Gibbs adds that two of the points which have been impressed upon him during the year are these—that very few of the cases of diphtheria appeared to be associated with defective drainage, and that in the early stage of the disease its "full infective force did not seem to be developed." These are points which are well worth recording. This report, which is a very thorough one, gives a short description of all the watercourses in the district and the steps which have been taken, or ought to be taken, to keep them in a cleanly condition. In connexion with the isolation hospital, Dr Gibbs makes a statement to which we are not quite able to subscribe—i.e., that the immunity of the nurses and attendants from infectious disease is due to having kept the air of the wards "constantly and thoroughly carbolicised." We notice that during the year there were 42 cases of diphtheria, 2 of cerebro-spinal fever, and 2 of typhoid fever admitted into hospital. None of these are diseases which, so far as we know at present, spread aerially, but even if this were so it is doubtful if carbolicising the air would act as a preventive. In our experience, the best safeguard as regards the nursing staff is to be found in carefully instructing the nurses as to the usual manner by which the disease is spread, and urging upon them the importance of avoiding unnecessary risks.

VITAL STATISTICS

HEALTH OF ENGLISH TOWNS

In thirty three of the largest English towns 6072 births and 4206 deaths were registered during the week ending April 1st. The annual rate of mortality in these towns, which had increased in the preceding three weeks from 19.6 to 20.9 per 1000, further rose last week to 21.2. In London the rate was 21.0 per 1000, whilst it averaged 21.4 in the thirty two provincial towns. The lowest rates in these towns were 12.8 in Swansea, 15.3 in Croydon, 15.5 in Hull, 17.3 in Brighton and 18.0 in Nottingham, the highest rates were 26.6 in Wolverhampton, 26.8 in Burnley, 27.7 in Salford, 29.3 in Preston and 29.8 in Bolton. The 4206 deaths included 433 which were referred to the principal zymotic diseases, against 406 and 423 in the preceding two weeks, of these, 119 resulted from whooping cough, 108 from measles, 65 from diphtheria, 55 from scarlet fever, 38 from diarrhoea, 31 from "fever" (principally enteric) and 17 from small pox. No fatal case of any of these diseases occurred last week in Swansea, Blackburn or Huddersfield, in the other towns they caused the lowest death rates in Derby and Birkenhead, and the highest rates in Portsmouth, Plymouth, Cardiff, Bolton and Preston. The greatest mortality from measles occurred in Hull, Cardiff, Newcastle upon Tyne, Portsmouth, Leeds, Preston and Plymouth, and whooping cough in Norwich, Burnley, Leicester, Liverpool and Manchester. The mortality from scarlet fever and from "fever" showed no marked excess in any of the large towns. The 65 deaths from diphtheria included 36 in London, 6 in Cardiff, 5 in West Ham and 4 in Preston. Five fatal cases of small pox were registered in London, 3 in Leeds, 2 in Halifax and 1 each in Derby, in Manchester and in Salford, 248 cases of this disease were under treatment in the Metropolitan Asylum Hospitals and 15 in the Highgate Small pox Hospital on Saturday last. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 2030, against 1147, 1965 and 1971 on the preceding three Saturdays,

235 new cases were admitted during the week, against 195, 180 and 225 in the previous three weeks. The deaths referred to diseases of the respiratory organs in London, which had been 338 and 394 in the preceding two weeks, further rose to 421 last week, but were 56 below the corrected average. The causes of 70, or 1.7 per cent., of the deaths in the thirty three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Bristol, Oldham, Sunderland, Newcastle upon Tyne and in seven other smaller towns, the largest proportions of uncertified deaths were registered in Cardiff, Nottingham, Liverpool, Salford and Sheffield.

HEALTH OF SCOTCH TOWNS

The annual rate of mortality in the eight Scotch towns, which had been 21.2 and 23.4 per 1000 in the preceding two weeks, declined again to 22.7 during the week ending April 1st, but exceeded by 1.6 per 1000 the mean rate during the same period in the thirty three large English towns. The rates in the eight Scotch towns ranged from 15.8 in Greenock and 16.5 in Edinburgh to 25.6 in Paisley and 26.8 in Glasgow. The 639 deaths in these towns included 60 which were referred to measles, 17 to whooping cough, 8 from diarrhoea, 5 from scarlet fever, 5 from "fever" 4 from diphtheria, and 1 from small pox. In all, 100 deaths resulted from these principal zymotic diseases, against 71 and 104 in the preceding two weeks. These 100 deaths were equal to an annual rate of 3.5 per 1000, which exceeded by 1.2 the mean rate last week from the same diseases in the thirty three large English towns. The fatal cases of measles, which had been 45 and 51 in the preceding two weeks, further rose to 60 last week, of which 40 occurred in Glasgow, 10 in Dundee, and 6 in Paisley. The 17 deaths referred to whooping cough showed a slight further increase upon recent weekly numbers and included 15 in Glasgow and 2 in Edinburgh. The fatal cases of scarlet fever, which had been 6 and 10 in the preceding two weeks, declined again to 5 last week, of which 3 occurred in Glasgow. The 5 deaths referred to different forms of "fever" showed a further increase upon those recorded in recent weeks and included 2 in Glasgow. The fatal cases of diphtheria, which had been 6 and 8 in the preceding two weeks, declined to 4 last week. The death from small pox was registered in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 136 and 151 in the preceding two weeks, declined again to 138 last week, and were 20 below the number recorded in the corresponding week of last year. The causes of 48, or nearly 8 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN

The death rate in Dublin, which had increased in the preceding three weeks from 25.2 to 26.7 per 1000, further rose to 27.9 during the week ending April 1st. During the thirteen weeks of the quarter ending on Saturday last the death rate in the city averaged 28.1 per 1000, the rate for the same period being 22.0 in London and 20.6 in Edinburgh. The 187 deaths in Dublin showed an increase of 9 upon the number in the preceding week, and included 7 which were referred to "fever," 3 to diarrhoea, 2 to whooping cough, 1 to scarlet fever, 1 to diphtheria, and not one either to small pox or measles. In all, 14 deaths resulted from these principal zymotic diseases, against 12 in each of the preceding two weeks. These 14 deaths were equal to an annual rate of 2.1 per 1000, the zymotic death rate during the same period being 2.2 in London and 1.2 in Edinburgh. The deaths referred to different forms of "fever," which had been 3 and 8 in the preceding two weeks, were 7 last week. The fatal cases of whooping cough, which had been 4 and 3 in the preceding two weeks further declined to 2 last week. The 3 deaths from diarrhoea exceeded the number in any recent week. The 187 deaths registered in Dublin included 26 of infants under one year of age and 50 of persons aged upwards of sixty years, the deaths of infants showed a decline, while those of elderly persons showed a further increase upon those recorded in recent weeks. One inquest case and 2 deaths from violence were registered, and 68, or more than a third, of the deaths occurred in public institutions. The causes of 15, or more than 8 per cent., of the deaths in the city last week were not certified.

result of a collision on horseback in the riding school. The patient being examined immediately in bed, one recognised at once the characteristic appearance of the injured knee (right)—the patella obliquely rotated on its vertical axis, firmly wedged in between the condyles, its surfaces directed laterally and its edges in an antero posterior direction, in addition, one could not help noticing the marked laterally flattened appearance of the joint, the limb being extended, and an entire absence of the rounded symmetry in the general outline of the knee. The outer edge of the "cap" could be felt projecting like the rim of a plate—a very unmistakable prominence. The patient stated that at the time of the accident he felt very severe pain, but on admission to hospital there was very little pain and tenderness. With the assistance of Surgeon C G D Mosse, reduction was effected by regulated pressure and gradual extension, there being no exaggerated degree of resistance from the extensor tendon or the ligamentum patellæ. The limb was fixed in a back splint and kept absolutely at rest for ten days, an ice bag was applied, and the patient was ultimately discharged from the hospital fit for duty and with no apparent ill effect to the joint. I have not been able to ascertain whether he ever experienced a recurrence of this dislocation.

"STRANGE INCIDENTS IN PRACTICE"

To the Editors of THE LANCET

SIRS,—I was very much struck with the article on "Strange Incidents in Practice," by Sir William Dalby, which appeared in THE LANCET of Feb 4th as a similar case of loss of speech with ability to communicate in writing came under my notice at the Colonial Hospital about five years ago. My patient was a middle aged sailor. He gave a vague history of an injury to his head on board ship. He understood everything that was said to him and was a strong and very active man. He could not speak a word and yet was able to communicate in writing without the slightest hesitation. Suspecting that he was malingering, I placed him under the influence of the A.C.E. mixture in order to ascertain if he would speak when going under or recovering from the anæsthetic. I took the precaution of placing a fellow patient in the room when the anæsthetic was given. At a certain stage in the inhalation the patient became voluble, but when he returned to his senses he was found to be still speechless. He continued to be speechless, although he was told that he had talked loudly under the influence of the anæsthetic, for about three weeks, when his speech was suddenly restored. I have met with another "strange incident" in hospital practice—viz., a fishbone in the sac of an inguinal hernia, when operating about three years ago to relieve a strangulation. I was therefore interested in finding that Mr Hutchinson has lately recorded a similar case.

I am, Sirs, yours truly,
T. H. DALBY, W.I. March 19th 1893

HENRY ALSTON

"THE TREATMENT OF HÆMORRHOIDS BY THE CLAMP AND CAUTERY"

To the Editors of THE LANCET

SIRS,—In THE LANCET of March 25th Mr H. Allingham remarks, with regard to the operation for hæmorrhoids by the clamp and cautery, that "it is at least four times as fatal as any other method of removing hæmorrhoids." This statement also occurs in the last edition of Allingham's "Diseases of the Rectum" (with the trifling variation that there the operation is stated to be six times as fatal).

During the last seven years I have seen many scores of cases of hæmorrhoids operated upon in the manner condemned by Mr H. Allingham and in no single case has either death or untoward symptom of any kind occurred. I would therefore venture to suggest to him that he should put before us both the figures and the source from which he obtained them, upon which he bases the statement that he has more than once publicly made. Until that course is adopted I for one cannot consent to look upon the fact as demonstrated. Further on in his letter he says, "Secondary hæmorrhage is likely to occur on

the separation of the sloughs caused by burning." This of course as it is put is a mere matter of opinion. I would ask Mr H. Allingham if he means to infer that, as a matter of fact, it does more frequently occur than when the ligature is used, and if so if he will quote his authority. I can hardly think that he means this inference to be drawn, as he goes on to say that "Tetanus secondary hæmorrhage are almost unknown now." Or does he mean that these terrible evils are the monopoly of the clamp and cautery? Indeed, it seems to me that the acrimony that has been imported into the debate on the relative merits of rival operations has somewhat obscured the pathological common sense of the disputants. Where the difference is from a pathological point of view between clamping the base of a pile and crushing it I have never, I regret to say, been able to see. Similarly, to declare that secondary hæmorrhage is more likely to occur from the separation of superficial sloughs after burning than from the separation of a ligature around the base of a pile is to me an exercise in pathological hair splitting of which my mind is incapable.

And now, finally, for a few facts. During the past four years it has fallen to my lot to see from 100 to 150 of Mr Henry Smith's hæmorrhoid cases both during and after the operation. Apart from the fact that none of them had a single bad symptom of any kind there were three points chiefly remarkable about them. Firstly, the extremely small amount of blood lost, so that in most cases the sheet on which the patient was lying was scarcely even soiled, secondly, the trivial degree of pain afterwards, for I have seen nearly all these patients the same evening as the operation and in only a very small proportion was any opiate required after the patient was put back to bed, and even then it was given more with the object of confining the bowels than of relieving pain, thirdly, the short time during which treatment lasted. The great majority of the patients were up and about in ten days and returned home on the fourteenth. Not half a dozen of the whole number required longer than this. As for the subsequent contraction and the other ills alluded to, Mr Henry Smith says that they are nowadays, like the excessive pain, purely imaginary. I am by no means an admirer of the "Procrustes' bed" method of treatment, at the same time I am unwilling that a method of treatment that I am convinced is in a very large number of cases entirely admirable should be so persistently decryd by those who clearly have not taken pains to make themselves intimately acquainted with it, as witness Mr H. Allingham's statement some weeks ago that Mr Smith cut off the pile and then applied the cautery, and Mr Smith's assertion that he has abandoned that practice for years in favour of simply burning it off. I am as ready to be convinced as anyone, and if the Messrs. Allingham can prove by the statistics of every case that has occurred to them, say during the last six years, that, as regards freedom from sepsis, pain, secondary hæmorrhage, subsequent contraction, and also as regards duration of treatment, the results obtained by the ligature or the crushing machine are better than those obtained by the clamp and cautery, they will at least have converted me.

"OCULO-MOTOR SYMPTOMS IN ORGANIC NERVE DISEASE"

To the Editors of THE LANCET

SIRS,—In a leading article of April 1st you remark "If a case of total ophthalmoplegia were observed in which the frontalis and orbicularis palpebrarum were affected whilst the lower facial muscles escaped, the clinical evidence for the hypothesis (viz. that these two muscles are centrally innervated from the oculo-motor nucleus) would be fairly complete. Dr Andrew Turner has not yet seen or heard of such a case." Such a case has recently been under my care, descended to me, together with his beds at the London Hospital, from the late Dr James Anderson. Knowing Dr Hughlings Jackson's interest in nervous disease, I have transferred the case to his care, but I have no doubt that Dr Turner could see it if he wished. I am in hopes that Dr Jackson will publish the case in full and consequently refrain from doing so myself without consulting him on the subject.

I am, Sirs, yours faithfully,
Christopher street, E.C., April 4th, 1893. FRED J. SMITH.

more satisfactory if the inventor had himself stood up to be fired at, and as no one, even in that case, would be emulous of firing at such a mark, it has been determined to test the properties of the invention by clothing pigs in it and shooting at them. There does not seem to be any doubt, according to the accounts of an expert, Captain Ziegler, that modern rifle bullets are completely stopped by the newly discovered material at a distance of 200 yards, but we have not yet received any particulars as to its weight and cost, or how it is to be worn, or whether it is hot and uncomfortable to wear or not. We shall soon hear, no doubt, what has been the result of the numerous experimental trials that have been instituted with the Lebel and Mannlicher rifles, and until these are published it may be well to reserve our judgment as to what is to be the practical outcome of the alleged invention of a bullet-proof fabric. Meanwhile, Herr Dowe is no longer alone in the field, for he has a competitor—also of Mannheim—named Reidels, and another in the person of an Austrian engineer named Sarneo. The invention is supposed to consist of a kind of light mail and hemp woven together. If it be heavy or at all cumbersome and likely to impede or interfere with the soldier's movements or comfort even, its use will obviously be of a limited kind, and we do not yet precisely know, as we have said, what might be the effect of a rifle bullet projected with enormous velocity when stopped by a resistant structure, as regards shock to the nervous system, bruising and rupture of internal organs and structures of the body generally. The great penetration of a bullet is caused by its high velocity, but the actual impact-effect of bullets of very small calibre on living tissues has yet to be determined. It is possible, if the alleged properties of these newly invented garments be experimentally proved to be well founded and if their power of resistance to the crushing effect of large and heavy projectiles be also established, that a new material has been obtained for defensive purposes which will altogether alter the aspects of warfare, but, so far as anything is actually known at present, there is much room for speculation and conjecture and but little for assertion based on knowledge and ascertained fact.

SIR JOSEPH FAYRER.

Our service contemporary, the *Army and Navy Gazette*, has an article on the career and services of this officer—whom we are glad to congratulate on being restored to good health and strength after his late illness—advocating that Sir Joseph Fayrer's services should be rewarded, at or before the end of his appointment as President of the Indian Medical Board, by a G.C.S.I. or a K.C.B. Sir Joseph Fayrer originally served in the Navy as an assistant surgeon before passing into the military service. He was at the siege of Palermo and that of Rome in 1847-48 and subsequently in the Burmese War and the Indian Mutiny and siege of Lucknow. Sir Henry Lawrence died in what is historically known as "Fayrer's House" at Lucknow. Sir Joseph Fayrer accompanied the Duke of Edinburgh and subsequently the Prince of Wales on their respective tours through India, and professionally distinguished himself in hospital and other work at Calcutta, so that his career has, at any rate, been sufficiently varied and not wanting in incident.

Correspondence.

"Audi alteram partem."

THE MEDICAL REGISTER

To the Editors of THE LANCET

SIRS,—I desire to draw attention to the difference in price which exists between the Medical Register and the Monthly Army List. The first-named book, the widespread diffusion of which is of real importance to the public in guarding them against deception, costs 6s. The Army and Navy Lists can be purchased for 1s. 6d. each. I propose that in addition to the existing large Register, a smaller and more portable edition of it be published quarterly, bound in paper like the Monthly Army and Navy List, and sold at a similar price. Such a book could be annually distributed to a four times greater extent to public officials than the present portly and unportable volume. It could be found in the minor registration offices and the minor police stations. 2 I

desire to point out the need of a local index to the Register. One long alphabetical register of the names of all the doctors in the three kingdoms exists, it is true, but one cannot verify names of doctors in localities without a local index, say, of country county or borough. I am told that the present form of the Register is that laid down by the Act governing registration. Doubtless this is so, but an index is an essential part of any book, and a local index seems to be needful in a book which contains in one long roll the names of the medical men of the three kingdoms and many hundred others practising either officially or privately in countries outside the British Isles. An Army List, with the names of all the officers in one long alphabetical list, would be a dismal and impracticable volume, the regimental grouping and general index solve the difficulty. In the Medical Register a local index would do a similar duty. If I wish to send a patient to a distant town or health resort, why should not the official register give me a borough or county list of the doctors living there? Surely Parliament never meant to veto such a provision. If it did the error needs rectification.

A cheap, widely diffused, frequently corrected register, showing deaths, expulsions, suspensions and local removal of medical men is one of the safeguards needed in a profession which is overcrowded and yet much overworked, which is doing enormous service for the State without recognition or reward by the State, and where unqualified men and adventurers seem to exist absolutely free from check.

I am, Sirs, yours faithfully,

Woolwich, April 4th, 1892.

GEORGE EYATT, M.D.

RICKETS IN AUSTRALIA

To the Editors of THE LANCET

SIRS,—A few years back you did me the favour to publish in THE LANCET some conclusions at which I had arrived, from clinical observations extending over many years, on the chief cause of rickets in this country. It appeared to me quite clear that the common idea that rickets is due to errors of diet is not supported by clinical experience. I have seen no reason to change the opinions I put forward then, but rather to feel more confirmed in them by subsequent experiences. The object of this letter, however, is not to draw attention to the conclusions above alluded to, but to encourage an independent inquiry into this subject by those who are practising in the Australian colonies. The fact that rickets is a malady that is as rare in its occurrence in those colonies as it is common with us has long been familiar to those who have been able to make comparisons, and the remarks made by Dr J. C. Verco of Adelaide at the Intercolonial Medical Congress of Australia in 1887 prove how deeply impressed he was with the singular absence of rickets in Australia and how fully he appreciated the inadequacy of the common theories which pretend to explain the cause of the malady. "There is some secret reason," Dr Verco remarked, "for this that we have not yet discovered." A few days ago I was favoured with a copy of the second edition of a small work on "Prescribing and Treatment for Infants and Children," written by Mr. Philip E. Muskett of Sydney, and special attention is directed by him to the subject of rickets in Australia. After reading Mr. Muskett's remarks I hope that you will allow me, through the medium of THE LANCET, to suggest to those who may feel disposed to investigate the question of the etiology of rickets in Australia to liberate their minds from the influence of any theories as to their causation and to be contented to observe fully, record accurately and attempt to prove nothing until they have collected their facts. What we want are clinical facts—not opinions.

I am, Sirs, yours truly,

ROBERT LEE.

April 3rd, 1893.

"DISLOCATION OF THE PATELLA 'EDGEWAYS'"

To the Editors of THE LANCET

SIRS,—Advertising to your correspondent's letter in THE LANCET of April 1st, in which he reports an instance of a rare and interesting dislocation of the patella, namely, dislocation by semi rotation ("edgewise"), I am reminded of an almost parallel case which came under my care whilst serving on the medical staff of the Army at Shorncliffe. In 1889 a healthy young cavalryman was brought to the station hospital with a report that he had "broken his knee," the

name the remaining unnamed ward in the hospital the "MacLagan Ward," in memory of the late Dr P M MacLagan.

Mr Mitchell of the Elswick Works, Newcastle, has given a further sum towards the extension and improvement of the University buildings, Aberdeen. The total of Mr Mitchell's donations amounts to £20,000

Newcastle-on Tyne, April 5th

SCOTLAND

(FROM OUR OWN CORRESPONDENT)

Medical Graduation

THE spring examinations in medicine at Aberdeen are finished, and the results have been announced. A large number of candidates presented themselves. Three gentlemen graduated M.D., and over forty passed the examinations for the M.B. and C.M. degrees. One gentleman took the diploma in Public Health, whilst the B.Sc. degree was conferred on no one. Messrs Ashley W Macintosh, M.A. and John Matheson, M.A., passed the M.B. examination "with highest honours," whilst Messrs Alex. Brown, M.A., B.Sc., and Alfred A. Moore graduated "with honourable distinction." The University gold medals were gained by Mr Alexander Don, M.A. (Fife Jameson Memorial in Anatomy and Shepherd Memorial for Systematic and Practical Surgery), Mr Robert Turner, M.A. (Keith for Systematic and Clinical Surgery), and Mr Ashley W Macintosh, M.A. (Matthews Duncan in Obstetrics). At the graduation ceremony Principal Sir William Geddes made reference to the munificence of Mr Charles Mitchell of Newcastle in presenting the University with £20,000 to aid the Building and Extension Fund.

The Medical Education of Women

For the last seven years medical education has been provided for women in Edinburgh where the licences of the Conjoint Scottish Colleges of Physicians and Surgeons have been obtainable by them. Now, however they have received a further concession to their demand for opportunity to secure access to the higher grade of the profession—viz., the M.D. The University Court of St. Andrews have acceded to an application lately made to them, and have, in virtue of the recently enacted ordinances, recognised the lecturers of that school as "lecturers specially appointed" by the University for the instruction of women in medicine. By this act the University have virtually constituted the school an outlying section of St. Andrews University and have empowered the students of that school to matriculate and to present themselves for examination for medical degrees after fulfilling a complete five years' curriculum of study. Moreover by the association of the College with the Leith Hospital ample clinical instruction is also secured.

April 5th.

IRELAND

(FROM OUR OWN CORRESPONDENT)

Monkstown Hospital

THE new buildings are now entirely free from debt, and the increased accommodation provided thereby has been fully taken advantage of and has enabled the staff through out the past year to keep pace with the increased demand for admission. The total amount of contributions received during the year was £1575 9s 6d, of which the sum of £130 was collected by ladies.

Health of Ireland December Quarter

During the last quarter of 1892 the births registered numbered 23,686 or 20.4 per cent., and the deaths 19,043 or 16.4 per cent. The birth rate was 1.0 per cent. under the average rate for the corresponding quarter of the past ten years, and the death rate was 0.3 per cent. below the average. The public health, measured by the statistics of mortality during the quarter, was satisfactory. The total deaths from the principal zymotic diseases were 1022, equal to an annual rate of 0.9 per 1000 living. No deaths from small pox were registered. Measles caused 125 deaths, against 232 for the preceding three months, scarlet fever, 105 deaths, or an increase of 18, typhus fever, 89, or 31 in excess, typhoid

fever, 184, against 153, whilst the mortality from whooping-cough was far below the average. Compared with the corresponding quarter of 1891 there was an increase of 84 in the average number of workhouse inmates on Saturdays during the quarter, but a decrease of 1908, or 3.2 per cent., in the average number of persons who received out-door relief.

The Water supply of Corl

Mr Donovan, medical superintendent officer of health, has directed the attention of the Public Health Committee to the contamination of the River Lee, which supplies the city. He states that it is most objectionable to have a dirty stream continuously flowing into the river and discolouring it for several yards in extent, more especially with an open sluice below, through which it more than likely finds its way to the reservoirs without being filtered. Mr Donovan's report has been referred to the Waterworks Committee.

Home for Protestant Incurables, Corl

This institution, which has now been in operation for twenty one years, has proved most successful for the purposes for which it was established. The Home is beautifully situated near Cork and supplies a want which is not met by any of the hospitals which abound in the adjoining city—it is at once a home for treatment and a hospital for the dying. The total receipts for the year were £1365 3s 3d, of which the sum of £59 11s 8d was received from pay patients. The capital invested now amounts to £11,500. The position of honorary assistant visiting physician and surgeon, vacant by the resignation of Dr Gibson, has been filled by the appointment of Dr Norman Townsend.

Mr M J Kelly of Castledermot has been placed on the Commission of the Peace for the county of Kildare.

The death is reported of Mr Robert Sanderson, M.D., M.Ch., which took place at Bella Vista, Edenderry, on the 3rd inst. Deceased was aged seventy seven.

April 4th.

PARIS

(FROM OUR OWN CORRESPONDENT)

French Surgical Congress

THE seventh session of this Congress was inaugurated on Monday, the 3rd inst., in the large amphitheatre of the Faculty of Medicine, under the presidency of Professor Lannelongue and the vice presidency of Professor Tillaux, the general arrangements being, as usual, supervised by Dr Pozza, the secretary. A large gathering of representative surgeons was present, amongst them I noticed MM Verneuil (now Honorary Professor of the Faculty of Paris), Baron Larrey, Chauvel (of the Val de Grâce Military School), Heydenreich (Nancy), Olier (Lyons), Boekel (Strasbourg) Stevenson (delegate of the British Government), Sir W Mac Cormac, Reverdin (Geneva), Roux (Lausanne), Jacobs and Lavissé (Brussels) Djemil Bey, Professor of the Imperial Faculty of Medicine of Constantinople, &c. The *clou* of the meeting was the inaugural address of the President, Professor Lannelongue, who, after having made a feeling reference to the scientific services of the late Professor Trélat, drew a striking comparison between the surgery of to-day and that of pre-Listerian times, when timidity on the part of the surgeon and scepticism on that of the public brought about the loss of thousands of valuable lives which the resources of modern surgery would have saved. "C'est que la chirurgie n'est plus à la merci d'un conseil de famille, elle n'est même plus mineure. Elle vient d'entrer dans sa majorité. Une confiance renaissante a fait taire le doute, et l'art, dégagé de toute pensée décevante, servi par tout ce qu'une jeunesse pleine de vie peut avoir de foi, a acquis une puissance d'expansion bien faite pour être l'objet de nos méditations." He recalled the words of the preface to Boyer's work on Surgery (third edition) published at the beginning of the century (1822). "La chirurgie a fait de nos jours les plus grands progrès et semble avoir atteint, ou peu s'en faut, le plus haut degré de perfection dont elle paraisse susceptible." What would Boyer say were he now alive? Modern surgeons said M Lannelongue in conclusion, know too much to fall into a like error. Fresh conquests lie within our grasp, new countries remain unexplored beyond the frontier already reached. The actual business of the Congress was then proceeded with, the following being a list of papers read: Dr Bouffin, of Nantes. Contusion of the Abdomen from a

THE CONDITION OF THE TEETH AS AN INDEX OF THE GENERAL STATE OF HEALTH

To the Editors of THE LANCET

SIRS,—The following editorial note appears in the last issue of the *British Journal of Dental Science*—

"In the House of Commons Mr S Smith asked the Postmaster General whether it was a compulsory rule that candidates for situations, after passing the Civil Service examinations, had to comply with the order of the medical officer to have such teeth extracted as he might require, sometimes as many as six or seven, without any guarantee that they would be then accepted, and whether without the extraction of such teeth they were rejected. Mr A. Morley said the medical officers were instructed to report officially with regard to the sight, the hearing and the teeth of candidates for appointment, *the state of the teeth being regarded as an indication of the state of the health*." [The italics are mine.]

There is material for extended comment in the above extract, but at the present moment I only wish to call attention to the italicised words, which, if literally interpreted, contain an error of no small importance. The condition of the teeth is not an index of the general health or powers of endurance of the individual. Every observant dentist is familiar with the fact that many persons of mature years who perhaps have never been in the enjoyment of perfect health and whose powers of endurance are comparatively low have nevertheless excellent teeth. The reverse is also true, many otherwise vigorous and healthy people having teeth of poor structure, which decay rapidly. It is of course true that the early loss of the teeth may lead to serious impairment of the health, but this is an avoidable evil and has no direct bearing upon the subject under consideration. If proper attention to the care of the teeth and efficient dentistry could be secured many candidates for Civil Service examinations having poor teeth might, on the whole, possess better qualifications than some of their successful rivals.

I am, Sirs, yours truly,

J. LEON WILLIAMS, D.D.S., L.D.S.

Bruton street, W., April 4th, 1893.

AFRICAN HÆMOGLOBINURIC FEVER

To the Editors of THE LANCET

SIRS,—Will you allow me to correct a misstatement of the remarks made by me on the above subject which occurs in the report of the meeting of the Epidemiological Society in THE LANCET of April 1st? I did not agree with Dr Manson "as to the non malarial nature of hæmoglobinuric fever." On the contrary, I have lately written a thesis to prove that this special form of fever is simply one of the manifestations of African malarial fever. I am not surprised that those who are not familiar with the forms of malarial fever as found in Africa should regard the fever under discussion as belonging to an entirely different class, but I believe that a knowledge of these gained on the spot would point to its obvious connection.

I am, Sirs, yours faithfully,

CHARLES F. HARFORD-BATTERSBY, M.D. Cantab

April 4th, 1893.

THE CHLOROFORM QUESTION

To the Editors of THE LANCET

SIRS,—The laboriously compiled report of THE LANCET Commission on Chloroform Administration published in your recent issues concludes that "the sequel shows that the method employed had very little influence in determining the result." This conclusion was *a priori* probable, seeing that the principle of administration was in all cases, with the exception of Junker's, the same. In all the chloroform was diluted by adding the air to the narcotic vapour on its passage to the lungs. It is obvious that an exact and constant dilution under such circumstances must be impossible. This fact may perhaps account for and explain the capricious action ascribed to the chloroform, in reality due to the uncertain method of administration. I have never yet been able to understand why the administration of chloroform from a towel should have been called the "open method." Perhaps it was because, there being a space left between the patient's mouth and the cloth, it was thought that plenty of fresh air would enter with the vapour. If so, then the superior

density of the chloroform vapour must have been lost sight of. As a matter of fact, it makes very little difference in a quiet atmosphere whether the cloth is held two, four or even six inches from the face. The vapour drops down in a more or less undiluted condition, often choking the patient, who thus finds himself deprived of his normal supply of oxygen. If, on the other hand, the cloth is held lower down or more to one side than usual, or if the room be draughty, the chances are that the patient only gets an occasional whiff of the anæsthetic. The first might be called the "closed" method and the latter the "open" method, but both terms are meaningless. The gist of the question is whether the chloroform is being administered from a controllable or from an uncontrollable reservoir. The only true open method is that in which there is absolutely no impediment to respiration, where the pure air on its passage into the lungs is diluted with a stated and controllable quantity of the vapour, the amount and strength of which can be graduated to suit the individual requirements. Inhalers answering this description have for some time past been on the market, and it is not until their use becomes general that we shall be enabled to ascertain exactly the action of the anæsthetic under given circumstances.

I am, Sirs, yours truly,

April 4th, 1893

SENEX.

** Our correspondent is mistaken in his assumption that the report of our Commission is concluded. Much yet remains to be published and we hope to continue the report next week.—ED. L.

NORTHERN COUNTIES NOTES

(FROM OUR OWN CORRESPONDENT)

Newcastle Nurses' Home and Training School.

DR PHILLIPSON presided at the annual meeting held last week of the Nurses' Home and Training School. The report showed that the staff consisted of sixty trained nurses and ten probationers, and that they had attended in all 586 cases. He referred in high terms to the valuable services of the matron and to the ability and conduct of the nurses, showing that the institution is an acquisition to the city and district.

Small-pox

There have been no further cases of small pox at Carlisle, but cases are still reported at Workington, Whitehaven and South Shields. At South Shields placards have been issued calling attention to vaccination, free stations for which have been opened in various parts of the borough.

Newcastle Natural History Museum

Several important additions have been recently made to this well known museum, including a fine specimen of the ruffed or Macqueen's bustard, as it is named in England, a native of Persia, Afghanistan, Western India &c., which, strange to say, was found feeding in a field near the coast at Marske-by-the-Sea last October, when it was easily approached and shot. This is the second specimen which has been recorded as taken in England. The first specimen was killed in Lincolnshire in October, 1847, and is now preserved in the York Museum. The Newcastle Museum has also received two kakas or brown nestor parrots, closely related to the keas, which have in recent years become one of the pests of the New Zealand sheep farmers, having acquired, by feeding on the offal at the sheep stations, a taste for mutton fat, to procure which they attack and destroy annually large numbers of sheep.

Scarborough

At a special meeting of the Scarborough Town Council held last week it was resolved to purchase a field about half a mile from the town at a cost of £1200 for the erection of a permanent hospital for infectious diseases, but the situation is outside the borough boundary and is therefore strongly objected to by the rural sanitary authority. The Seaboard Harbour local board have also decided to build a permanent infectious diseases hospital for their town.

Berwick Infirmary and Dispensary

At a meeting of the governors of the Berwick Infirmary and Dispensary held last week it was stated that 400 patients had been attended to and that there was a satisfactory balance in hand of over £100. At the same meeting it was agreed to

medical students in this city is close upon 600. With us, as with you, the complaint is, "the profession is overstocked."

New Hospitals

In the fall of last year a new hospital was opened in Toronto under the auspices of the Roman Catholic Church. St. Michael's Hospital is under the care of a Mother Superior, with a staff of religious and professional nurses. In Montreal progress is being made in the completion of the Victoria Hospital, additions have been made to the General Hospital and during the past month a wealthy citizen has donated some \$30,000 to establish a convalescent hospital for the city.

Miscellaneous

The *Ontario Medical Journal* is the last addition to the list of medical publications. The publishers receive a subsidy of \$600 from the College of Physicians and Surgeons per annum, furnishing each member with a copy monthly.

The medical men attached to our militia have formed an association with the object of attaining their proper status and rank and the discussion of subjects more particularly interesting to themselves. The first president is Surgeon F. W. Strange of Toronto.

The Royal Medical College, Kingston, which for so many years has been a separate institution, has joined its fortunes with Queen's University as its medical department.

The Toronto Clinical Society is the latest addition to our medical societies: the members being known as Fellows and classed as resident, non resident and corresponding. The president is Dr. J. Algernon Temple.

March 4th.

AUSTRALIA

(FROM OUR OWN CORRESPONDENT)

The Management of Australian Hospitals

THE hospital question has assumed an acute stage in our two principal cities. The two large hospitals in Melbourne are unable to pay their way: the Sydney Hospital is deeply in debt and the Prince Alfred Hospital Sydney is, according to a recent statement of Sir Alfred Roberts in an "alarmingly state of bankruptcy." The hospital at Broken Hill has no funds and the committee threaten to close it. The crisis has been brought about by the falling off of the voluntary subscriptions caused by the general depression in trade which is passing over the Australias. Australian hospitals are in the main State institutions. Parliament votes the money to build them and they are supported largely by State grants. The system in vogue in most of the colonies provides that, once built and equipped, the hospital is to be supported by voluntary contributions and aided by a State subsidy equal to the amount of voluntary contribution. The large metropolitan hospitals are treated on a somewhat different plan. They receive a pound per pound State subsidy on their voluntary contributions and in addition, a substantial sum is yearly awarded by Parliament, they are, moreover, paid a weekly allowance for all patients recommended by the Government medical officers. This special treatment of the large metropolitan hospitals is necessitated by reason of the sloth and jetsam of the suffering humanity of the colonies being swept into the great cities. Of late, owing to the general mercantile depression, the voluntary subscriptions have enormously decreased, and as a consequence the State subsidies have not been paid. The upset in trade has on the other hand thrown large numbers of workers out of employment and destitution and disease have correspondingly increased. Thus at the very time when the heaviest demands are being made on the resources of the hospitals the directors find themselves compelled to shut up their wards and refuse admittance to the suffering poor.

The Melbourne Hospital has an overdraft of £20,000 at its bankers, the wards are full, the creditors are pressing and there is no immediate prospect of its being able to pay its way. The committee having been brought face to face with this deplorable condition have been inquiring into their expenditure, and although no special report has been made it is understood that there have been found many reasons for retrenching. The Sydney Hospital is in a similar position. A few years ago Parliament came to the assistance of the directors and paid off a large overdraft, and now they find themselves again in the mire

with an overdraft of £15,000 hanging round their necks. Of late years there has apparently been a great want of economy, and at a recent meeting of the directors the opinion was expressed that the medical staff were to blame "for treating their patients too well" and for ordering too many "extras." It has been suggested that the large increase in the cost of patients is due to the heavy protective tariffs recently imposed in New South Wales, but a close examination of the matter shows that that is not the only cause. This point is well demonstrated by comparing the annual cost of patients in the Sydney Hospital with that of the Newcastle Hospital. This is the largest provincial hospital in New South Wales. It supplies the wants of a mining, manufacturing agricultural and shipping community of seventy or eighty thousand people and is not excelled by any Australian hospital in efficiency and general results. A return prepared by the late medical superintendent shows that at that hospital the annual cost per patient in 1887 was £64 18s 3d and in 1892 £70 15s 4d whilst in the Sydney Hospital the same item was represented by £25 10s 9d in 1888, and by £32 13s 3d in 1892. The Sydney Hospital directors have appointed a financial sub-committee to investigate the state of affairs. In the meantime they have set about retrenching by cutting down the salaries of their principal officers. Hitherto the medical superintendent received £500 a year and he was responsible for the efficient and economic working of the institution. The committee's idea of retrenchment is manifestly nebulous. They appear to think that by reducing their chief administrative officer's salary to £300 a year and by appointing—as they must at that salary—a man who will have the status of a senior house surgeon they are making a proper reduction in their large expenditure. With a fairly large experience of hospital management I venture the opinion that the first step towards economy and efficient administration should be the appointment of a resident medical superintendent with large powers at a salary more nearly approaching £1000 than £500 a year. It will be interesting to watch this new departure at the Sydney Hospital. Two other hospitals that are in great financial straits are the Alfred Hospital at Melbourne and the Prince Alfred Hospital at Sydney. The directors of the Melbourne institution are so deeply in debt that they have had to close nearly half of the free beds and to run the wards on the paying system. There also the medical staff are supposed to be in some way or other the cause of the extravagance, and the directors at a recent meeting passed a special resolution asking the honorary medical officers to assist them in economising. The resolution expressly called attention to the large quantity of stimulants used.

Obituary.

ARTHUR J. CRIBB, M.D. LOND., M.R.C.S. ENG., L.S.A., HIGHBURY.

THE death of Dr. Cribb, at the comparatively early age of fifty-eight, removes from Highbury one of its best practitioners, well known to the profession of London far beyond his immediate sphere of practice. He had been in practice in Islington for over thirty years, first as the partner of Mr. Macrae of Compton terrace, he himself then living at Cloudesley terrace, Liverpool road, thereafter removing to Compton terrace and then to Highbury place. After the death of Mr. Macrae he was joined in partnership by Mr. Malcolm Morris who since then has devoted himself to another branch of practice. On the dissolution of this arrangement he took into partnership Dr. Phelps, who has continued in the practice till the present time.

The parish of Islington, one of the largest parishes in England, has grown much in the time covered by Dr. Cribb's active life, and his practice extended to all parts of it and beyond. His health, especially for the last fifteen years, was liable to grave and long interruptions. But this circumstance only seemed to call out the intense energy of his character and as soon as his attacks of illness were over sufficiently to let him step into his carriage he was amongst his patients again. Large practice done under such conditions for thirty years is itself a heroic achievement under which ordinary men succumb very quickly. Dr. Cribb was a graduate of the University of London and used to trace some of

Kick of a Horse, Intestino-Peritoneal Septicæmia, Indications for Operative Treatment. Dr Panné (Nevers). A series of Seven Tarsectomies for Equino varus Dr Reynier (Paris) Supporting Hydatid Cyst with Concomitant Peritonitis, Laparotomy, Recovery Dr Martel (St. Malo) Stalk and Ear of Corn in the Male Bladder, Successful Suprapubic Lithotomy, Presentation of the Extracted Foreign Body Dr Tuffier (Paris) Remote Results of Renal Surgery Dr Fôvrier (Nancy) Resection of the Superior Maxillary Nerve and Meckel's Ganglion by a Temporal Incision for Obstinate Neuralgia of twenty-one years' standing and localised to the second division of the fifth pair. The proceedings of the Congress will be continued every day up to Saturday next inclusively, morning and afternoon sittings being fixed for 9 A.M. and 2 P.M. respectively

The Frequency of Arterial Degeneration amongst British Soldiers and Sailors its Cause

The common occurrence of aneurysms of the large arteries in the ranks of the British army and navy has formed the theme of innumerable communications. Thus in 114 post mortem examinations conducted at Netley by Davidson atheromatous changes were noted in 22, no fewer than 17 of these subjects having had syphilis. Of 78 non syphilitic subjects only 4 presented atheromatous degeneration. Another observer, Welch,¹ arrives at the conclusion that syphilis is to be credited with the production of the aortic aneurysms so often to be seen in barrack hospitals. Most British writers agree with Welch and Davidson in holding syphilis, together with alcoholism, responsible for aortic aneurysms. In a lecture recently delivered by Dr Lancereaux at the Hôtel Dieu, that pathologist traverses these conclusions, and remarks, in reference to Welch's statement, that in sixty-four of his hundred cases of aneurysms of the aorta the first part of the arch was affected, that the lesion was more common amongst men who had passed some time in foreign service, and that the arterial mischief is probably due to malaria and not to alcoholism or syphilis. For many years past M. Lancereaux has taught that the syphilitic virus manifests a special predilection for medium sized arteries provided with lymphatic sheaths (more especially the cerebro-spinal arteries), whilst the larger vessels, such as the aorta and its principal branches, are generally spared. When in a young syphilitic subject the aorta presents a dilatation *en cul-de-sac*, and the lesion is circumscribed within narrow limits, its syphilitic origin may be admitted, but M. Lancereaux believes that the majority of aortic aneurysms, wanting as they are in the above characteristics, are either due to generalised arterio-sclerosis or to malarial influences (*aortite en plaques*).

An Undescribed Cause of Dystocia

In a paper appearing in the *Loire Médicale* Dr Blanc calls attention to a cause of dystocia hitherto unmentioned in treatises on midwifery. The cause resides in the abnormal softness of the fetal head from arrest of ossification. The practitioner is called to a case where the normal conformation of the pelvis and the equally normal development of the foetus promise, with the coöperation of good and regular pains, a speedy delivery, but the head makes no progress, uterine inertia supervenes and instrumental aid is necessary to effect delivery. In these cases the incompletely ossified head can be felt by the exploring finger to present an abnormal softness of the bones, parchment crepitation being yielded on pressure, the fontanelles are unusually large and the sutures are abnormally wide. The practitioner has to deal with a soft head (*tête molle*). Irregularity of descent, flexion &c., are the result, and the resistance of the perineal floor is not overcome as by a head possessing the usual firmness. As soon as the diagnosis is made recourse must be had to the forceps.

Congress of the Aliens of France and of French speaking Countries

The annual meeting of this Association will be held at La Rochelle from Aug 1st to 6th. The special subjects of discussion will be Auto-intoxications in Mental Affections and False Evidence by Lunatics in Courts of Justice.

A New Treatment of Area (Alopecia Areata)

In France the above disease is known by the name of *pelade* and its parasitic origin is pretty generally accepted. Dr Pye Smith opines that many of these cases of *pelade* are in reality examples of ringworm in its later stages. However

that may be, the practitioner will be glad to be made acquainted with the most recent treatment in vogue in Dr Hallopeau's wards at St. Louis Hospital. When the affection is limited in extent rapid cure is obtained by repeated applications of cantharides solution with daily use of a 90 per cent. carbolic lotion. Where the disease is more diffused (all the hairy parts of the body or the entire scalp) the following lotion gives good results. Alcohol, 100 grammes, essence of turpentine and camphor, of each 20 grammes, corrosive sublimate, 10 centigrammes. Local patches have been successfully treated by M. Hallopeau by the application of essence of wintergreen, which produces no irritation or pain.

April 4th

BERLIN

(FROM OUR OWN CORRESPONDENT)

Congress of German Hygienists

A CONGRESS of German Hygienists met at Dresden on March 24th. At the first sitting Dr Sturm of Berlin spoke on the nature of personal predisposition and its relation to place and time. He declared the comma bacillus to be a mere play thing, and the part it plays in the etiology of cholera as but small. It produced an effect only in cases of personal predisposition. At the second sitting it was resolved to lay the draft of a "System of Public Hygiene" before the Imperial Government. The Congress also empowered one of its members to prepare a manual of hygiene, to be published at the instance of the Hygienists' League, with a list of the names of its members. There was also a long discussion of the Imperial Epidemic Bill, which was severely criticised. The proposals of the Congress for its modification, including a protest against all measures of disinfection except in the case of dirty linen, are to be forwarded to the German Government. The Congress also expressed the opinion that, if properly treated, cholera is not more dangerous than typhus fever or pneumonia. The Congress relied for the protection of the population against infectious diseases and epidemics upon the introduction of a new system of personal and public hygiene, including the propagation of the knowledge of the laws of health, with a view to the annihilation of the most important cause of disease in individual predisposition. To this end the Congress appointed a committee to draw up a memorial to the Reichstag and the Federal Council. At the same sitting Dr Hübner of Leipzig stated that he had applied to Count Zedlitz, the last Prussian Minister of ecclesiastical, educational, and medical affairs, with the offer to prove the curability of small pox, but he had been referred to Professor Koch's experimental hospital, from which he had received the answer that the arrangements of the hospital did not allow Professor Koch to pay regard to individual opinions.

The International Sanitary Conference

A considerable number of the delegates to the International Sanitary Conference, now deliberating at Dresden, went last week with Professor Koch to see the Nietleben Asylum, near Halle, the scene of a recent cholera epidemic.

In Ophthalmological Society

An Ophthalmological Society was founded here lately.

Professor Karl Friedrich Rammelsberg, the oldest of the German chemists of mark, received a large number of congratulatory letters and telegrams on the occasion of his eightieth birthday last Saturday.

Dr David Wiener, Privy Counsellor on Sanitary Affairs, died the other day at Graudenz, aged sixty-seven. He enjoyed a considerable reputation as a writer on forensic medicine and matters of sanitary police. He wrote a manual of the medical legislation of the German Empire and of the States of which it consists, a collection of medico-legal opinions and contributed to the *German Medical Weekly* and the *Periodical for Medical Officials*.

Women Candidates—Kate Isabel Clatterback, Ldith Ellen Goodrich, Mary Philip Graham, Sarah Kemp, Elizabeth Dorothea Lyness, Judge Speirs Maclean, Mary Rose Riddall, Roberta Henrietta M. Stewart.

The following have passed the under noted portions of the first professional examination for the new degrees of Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch.B.)—

1. In *Anatomy and Physics*—George MacLellan Blair, William Adam Burns, John Laird Simpson, Matthew Logan Taylor.
 2. In *Anatomy and Chemistry*—Andrew James Smith.
 3. In *Zoology and Physics*—Robert Carswell M.A., Walter S. Noble Findlay M.A., Donald M. Kinlay, James M. Queen, M.A., James M. White, Robert White.
 4. In *Zoology and Chemistry*—David Louisa Cairns, Francis James Charteris, James Duncan Cochran, Samuel Macfarlane Sloan.
 5. In *Physics and Chemistry*—Douglas Swan.
 6. In *Dental*—Alexander Smith, Allan Murdoch Macdonald, William Wylie.
 7. In *Zoology*—James Strang.
- Women Candidates**—In *Physics and Chemistry*—Mary Gardner, Jessie Hawkesworth Smith.

The following have passed the second professional examination for the degrees of Bachelor of Medicine (M.B.) and Master in Surgery (C.M.)—

Robert Aitkenhead, Arthur Roband Anderson, John James Anderson, Thomas Angus Alexander Blair, James Boyd, William Burns, James Souter Christie, Allen Aiken Clark, James Donaldson, John Sharp Douglas, John Drummond, Richard John Edwards, Wm. Bickerton Edwards, Samuel Enclish, Daniel Ferguson, Albert Alfred Finkelstein, James Forrester, Andrew Fleming Galloway, John Guy, James Henry Francis Robert Hill, John Affleck Hope, Albert Bures Hughes, John Hunter, David Kerr, William James Kerr, William Henry Lang, Arthur Lawton, David Lewis, James Duncan Lore, James William Otto van Millingen, John Morton, George Bain Murdoch, John Murray, Daniel M. Coll, William M. Cormick, Donald MacDonald, John M. Laws, Misses Neil MacLay, Samuel M. Leas, Farquhar Macrae, Archibald Russell, Oliver Wallace Ainsworth, Pride Daniel Richmond, Alexander Shearer, Hugh Stevenson, James Stewart, Ernest Frederick Docetti Walker, James Wells.

Women Candidates—Alice Lilian Louisa Cumming, Margaret Cochran Dewar, Marion Gilchrist.

SCHOOL OF PHYSIC, TRINITY COLLEGE, DUBLIN—First Examination in Medicine: First prize, David F. Walker, second prize, Michael J. Smith, first honours, William S. Haughton and R. Travers Smith.

MEDICAL MAGISTRATE—The Lord Chancellor, on the recommendation of Lord Rothchild, has appointed Mr. S. Osborn, F.R.C.S., a magistrate for the county of Bucks.

TYPHOID FEVER AT MOSTYN—Some alarm has been created by an outbreak of typhoid fever at Mostyn in a district of which at least eleven cases have already been reported. Energetic measures have, under the advice of Mr. James Williams, medical officer of health, been at once adopted.

ROYAL BRITISH NURSES' ASSOCIATION—On the 5th inst. a meeting was held at Edinburgh for the purpose of receiving a deputation from this Association in favour of a proposition to establish at Edinburgh a branch of the society. Dr. Bezy Thorne and Dr. Bedford Fenwick spoke on behalf of the Association and explained its objects. On the motion of Dr. Douglas MacLagan, seconded by Dr. Underhill, it was resolved that a Scottish branch of the Association be formed at Edinburgh. Some discussion arose on the question as to whether one year's training in hospital, with a subsequent connexion of two years in a training institution, should not be considered sufficient and this view, on the motion of Dr. Peel Ritchie, was recommended for adoption by the London authorities.

FORFARSHIRE MEDICAL ASSOCIATION—At a quarterly meeting of the members of this Association held at University College, Dundee, Dr. Rorie the President spoke of the loss sustained by the Society by the death of Dr. Macleod, who had been one of its most active members, and who for four years had acted as treasurer. The secretary was instructed to record an expression of regret in the minute-book. Dr. Pirie then showed a typical case of Pseudo-hypertrophic Paralysis which had been previously exhibited to the Association. Several pathological specimens were then brought before the members. Dr. Kynock showed a Three Months Pregnant Uterus and Appendages removed from a patient who had died of acute tuberculosis, Dr. Rorie exhibited specimens of Bony Spicula in the Dura Mater from two epileptic patients, Dr. Mackie Whyte showed the Liver, Spleen and kidneys from a case of waxy disease and also specimens of Aneurysms. Finally, Dr. McGillivray showed a series of Ophthalmic cases, and read notes of three cases of Metastatic Parental Choroiditis.

The annual meeting of the National Health Society for the distribution of medals and certificates to the successful competitors at the Society's Medal Examination, is arranged for June 3rd at Grosvenor House, by the kind permission of his Grace the Duke of Westminster, who, with the Duchess, has consented to be present.

FOOTBALL CASUALTIES—A youth whilst playing a game, on the 27th ult., at Stockton Heath Warrington, fractured his arm. On Saturday last, during a League match, at Burnley, a goal keeper sustained an injury to the face, part of the cheek bone being "splintered," he was removed to the Burnley Hospital. On the same day, in the course of a match in Nelson's field, Low road, Hunslet, a youth, aged seventeen years, fractured his leg, and was conveyed to the Leeds Infirmary. On Monday last, at Hanson lane, in a match Halifax against Hull, a player fractured his clavicle.

NOTES IN PARLIAMENT

Death Certification.

The Select Committee of the House of Commons appointed on the motion of Dr. Cameron to inquire into the question of death certification met on the 28th ult. to select a chairman and arrange the method of procedure. The choice of chairman fell upon Sir Walter Foster, Parliamentary Secretary to the Local Government Board, Dr. Cameron being the member who proposed him. It was arranged that the first meeting of the Committee for the hearing of evidence should be held on Friday April 14th and that thereafter there should be meetings twice a week on Tuesdays and Fridays. In the first instance inquiry will be directed to the present state of the law as to registration and burial and afterwards to suggested improvements. The members nominated to the Committee are Sir Walter Foster (chairman), Mr. Arch. Mr. Brookfield, Dr. Cameron, Dr. Farquharson, Mr. Hozier, Mr. Heywood Johnston, Sir Thomas Lea, Mr. MacNeill, Sir Stafford Northcote and Sir Henry Roscoe. The Committee have the usual powers "to send for persons, papers and records."

The Oldbury Vaccination Cases

After the recess Mr. Hopwood will address a series of questions to the President of the Local Government Board with reference to the alleged cases of injury by vaccination at Oldbury in the West Bromwich Union. Mr. Hopwood's immediate purpose is to secure for the benefit of the board of guardians a copy of the report on the subject made by Dr. Acland to the Royal Commission on Vaccination. His information is to the effect that the report though repeatedly asked for, has been refused.

Resumption of the Session.

After an Easter holiday of less than a week the House of Commons resumed its work on Thursday when there was a very large attendance of members. The House of Lords does not meet until Tuesday, the 18th inst.

Seamen's Provisions Bill

In view of the Committee stage of this Bill a large number of amendments have been placed upon the notice paper of the House of Commons. Mr. Lawrence has given notice of two new clauses. One is to the effect that in case the supply of butter, marmalade and jam, or any of them runs short, or it is impossible to procure them one pound of salt meat and one pound of preserved meat may be issued in lieu of the full rations of these articles and proportionately for lesser rations. The other is to the effect that it shall be lawful for the master and crew to mutually agree at any period for substitutes other than those provided in the schedule of the Bill. Mr. Havelock Wilson has drawn up a new clause providing that the Bill shall not apply in certain circumstances to Asiatics or Africans or to ships where by mutual consent, no food is provided for the crews but an allowance of money given weekly as an equivalent.

Appointments.

Successful applicants for Vacancies Secretaries of Public Institutions and others possessing information suitable for this column, are invited to forward it to THE LANCET Office directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.

ALLEN JAMES M.R.C.S. L.S.A. Lond. L.R.C.P. L.V. Edin. has been reappointed Medical Officer of Health for the Bollington Urban Sanitary District.

ARMISTEAD, H. W. M.R.C.S. L.R.C.P. has been appointed Senior House Surgeon to St. Bartholomew's Hospital.

BASHALL, C. E. L.R.C.P. M.R.C.S. has been appointed Assistant House Surgeon to the South Devon and East Cornwall Hospital Plymouth.

BATES J. CURTIS M.R.C.S. L.R.C.P. Lond. has been appointed Medical Officer to the Croydon Board of Guardians for the Norwood District.

BRIDGES, E. C. M.R.C.S. L.R.C.P. has been appointed Junior House Physician to St. Bartholomew's Hospital.

the symptoms of his ill health to the strain of the examinations for that degree. In practice he was courteous, ready, original and energetic. He was esteemed and beloved by his patients. He had his peculiarities and even his faults like other men, but he had great virtues, which were displayed in all the relationships of life from those of his family downwards. In the affairs of the parish, of the Church, and of the Parliamentary division, he took an active and intelligent interest. Of late years he had added to his other duties that of Medical Lecturer to the Church Missionary College Islington. Dr Cribb was the son of the late Mr John Jennings Cribb, who practised medicine at Cambridge. Amongst the facts of his earlier history were his education at the Middlesex School and his house surgery at Middlesex Hospital. He was also house surgeon to the Tunbridge Wells Infirmary. For many years after commencing practice he was one of the most active members of the honorary staff of the Holloway and North Islington Dispensary and up to the time of his death he continued to be one of the most valuable members of the committee. He took much interest in the Society for the Relief of Widows and Orphans of Medical Men, and in other benevolent agencies of the profession. Any notice of Dr Cribb in our columns would be incomplete without some account of his many illnesses, which were of a somewhat unusual character and which included a history of one or more intense attacks of renal colic, and in later years—say the last twelve or fifteen—attacks of hæmatemesis and melæna, with or without ascites at varying and, latterly, shorter intervals. Throughout the whole of his life he was attended, kindly and constantly, by his neighbour Dr Stokes. At a post-mortem examination the following facts were observed.—The peritoneum was found to be thickened and opaque, with firm adhesions uniting the various organs together and the viscera to the back of the hard abdominal wall, which at points was like a solid plate. The spleen was considerably enlarged. Other organs were apparently healthy. The abdomen was the only cavity examined. The pylorus was of normal size, and no evidence of malignant new growth could be detected. Dr Cribb leaves a widow, two sons and two daughters to lament his death.

PROFESSOR ALESSANDRO SOLIVETTI

PSYCHOLOGY is one of the strong points of Italian medicine, and few have done it more credit than the able and industrious vice director of the great Roman Manicomio and professor of clinical "psichiatria" in the University who died on the 26th ult. Dr Solivetti had worked long and well in the institution with which he was connected, first under the late lamented Dr Fiorispini, of whose exemplary career we lately gave some account, and next under Dr Fiorispini's highly efficient successor. Shortly after graduation he made a round of visits to the leading medical schools of Germany and France, studying particularly their asylum systems and keenly noting anything novel or serviceable in their management. He returned to Rome one of the most accomplished alienists in Europe and for thirty two years dedicated all his time and means to perfecting the care and cure of the insane in her chief asylum. He was as already indicated, Dr Fiorispini's "right-hand man," beloved by his chief and by his staff of assistants beloved too, by successive relays of the students, who flocked to his prelections in the "Sapienza." Personally he was a most amiable and agreeable man and he will be long missed by those with whom he lived and laboured in Rome and its province. He was but fifty seven when he died.

METROPOLITAN ASYLUMS BOARD—The number of patients remaining in the several fever hospitals of the Board at midnight on April 4th was as follows.—Eastern Hospital, 123 scarlet fever, 51 diphtheria and 4 enteric fever, North Eastern Hospital, 491 scarlet fever, North Western Hospital 157 scarlet fever 104 diphtheria and 7 enteric fever, Western Hospital, 211 scarlet fever, 36 diphtheria, 1 typhus fever and 7 enteric fever, South Western Hospital, 213 scarlet fever, 42 diphtheria and 13 enteric fever, South Eastern Hospital, 247 scarlet fever, 23 diphtheria and 12 enteric fever, Northern Hospital, 526 scarlet fever and 12 diphtheria. There were on the same date 147 cases of small pox on the hospital ships *Atlas* and *Cestria* and at Gore Farm 99 cases.

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.—The following gentlemen passed the Second Examination of the Board at the meeting of the examiners on the 1st inst.—

Anatomy and Physiology—Arthur C. B. Pierson Thomas Spencer Henry Bailey and Ernest J. A. Dodd students Yorkshire College Leeds Edward V. Worthington and George E. F. Stammers, Bristol Medical School Charles R. Dykes Bristol Medical School and Mr Cooke's School of Anatomy and Physiology Daniel Pettigrew and William H. Oxley Sheffield Medical School, Robert E. Cran William T. Burns and Arthur C. Oldham, Owens College Manchester John H. Clements Mason's College Birmingham Edward H. Roberts St. Mungo's College, Glasgow John G. McKay Melbourne University, Frederick J. L. Willey Melbourne University and Bristol Medical School George E. Dodson, St. Bartholomew's Hospital, John Gorman Queen's College, Belfast John R. Johnson University College Liverpool.

Anatomy only—Alfred A. P. Moffatt, Owens College, Manchester William F. Maw, Edinburgh University and Yorkshire College Leeds Francis R. M. Higgs John C. Rneale and William H. Tracy, Mason's College Birmingham Frederic Anthony Bist Medical School Richard E. W. Jennings Bristol Medical School and Mr Cooke's School of Anatomy and Physiology Edward H. Herring Middlesex Hospital Ernest G. L. Goffe University College and Quinlan's School, St. Thomas's Hospital.

Physiology only—Herbert Eng and Herbert Hallam, Sheffield Medical School Thomas MacDonell, Queen's College, Belfast Stanley W. Williams University College Liverpool John I. Elliott Yorkshire College Leeds Thomas Jones Owens College Manchester William L. Freer Mason's College, Birmingham Edward Fielden, Durham University and Owens College Manchester.

Nine candidates were referred in both subjects, three in Anatomy only and nine in Physiology only.

Passed on the 3rd inst.—

Anatomy and Physiology—Percy G. Lodge student Yorkshire College Leeds H. R. Webb Ware Oxford University James Tempest Owens College Manchester Stanley Stephens, St. Mary's Hospital George V. Worthington Cambridge University John H. Fenoull, Cambridge University and St. Mary's Hospital John A. O. Briggs and William R. Stowe St. Bartholomew's Hospital Robert O. Moon and William A. Horton Guy's Hospital John H. Crowley, Melbourne University and Kings College Hospital Arthur D. Ketchum University College William I. Woodhouse and Rupert Wheatley Middlesex Hospital Charles R. Meyer St. George's Hospital Frederick H. Atkinson and Abraham I. Roz Saar Charing Cross Hospital.

Anatomy only—Edmund B. Lloyd, St. Mary's Hospital John I. Ferrie St. Bartholomew's Hospital, and Arthur G. Ede University College.

Physiology only—Edwyn R. Grazebrook Kings College Albert V. Merton, Owens College Manchester Charles O. Grummitt Francis H. Martin, Robert A. Draper, Cambridge University John B. Stanfield, Oxford University James O. B. Brain Hartnell Middlesex Hospital, Alexander Baker, St. Thomas Hospital Harvey Hillard Charing Cross Hospital, and Sydney Crispin Mason's College, Birmingham.

Seven candidates were referred in both subjects nine in Anatomy only and five in Physiology only.

Passed on the 4th inst.—

Anatomy and Physiology—William Ryan Albert W. Herby William M. Jones and Howard Green, students of Charing Cross Hospital Walter P. Jones and Sidney F. Smith St. George's Hospital Nora Daly Victor E. Collins Arthur J. Dolman, Harry T. Hicks Harry L. Williams and George K. Levick, Guy's Hospital Michael Takayan Richard W. Western, Allan Warner, Edward H. Sucliff, St. Thomas's Hospital Justus M. Schnur Robert M. Cowie and William B. Bell Kings College Arthur J. H. Boyton Alexander B. Tucker and Arthur Heath St. Bartholomew's Hospital William G. Savage, University College.

Anatomy only—Edmund S. Hall and Eric N. Scott, Guy's Hospital Thomas B. Marshall St. Thomas's Hospital Quintin H. Mille Charing Cross Hospital and Edward B. James, St. George Hospital.

Physiology only—Thomas A. Barton and Bernard Rowland St. Bartholomew's Hospital, Frederic W. Page St. Thomas's Hospital Robert I. Brown Guy's Hospital, and Daniel B. Becker St. Charing Cross Hospital.

Three candidates were referred in both subjects five in Anatomy only and five in Physiology only.

UNIVERSITY OF GLASGOW—The following have passed the first professional examination for the degrees of Bachelor of Medicine (M.B.) and Master in Surgery (M.Ch.)—

Notes, Short Comments & Answers to Correspondents.

EDITORIAL NOTICE

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office

Lectures, original articles, and reports should be written on one side only of the paper

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub Editor"

Letters relating to the publication, sale and advertising departments of THE LANCET should be addressed "To the Publisher"

We cannot undertake to return MSS not used

PUBLISHER'S NOTICE

IN order to facilitate the work of reference to the volumes of THE LANCET, we have arranged in the future to publish duplicate copies of the Index to each half yearly volume in a form in which they may be subsequently filed or bound together

We have had a large number of duplicate copies of the Index to the last half yearly volume printed, and those of our subscribers who may wish to be supplied with loose copies can obtain the same (without extra charge) on making application to the Publisher of THE LANCET

DOUBTFUL DIAGNOSIS AND THE INTERVENTION OF THE MEDICAL OFFICER OF HEALTH

Mr. Henry Brand.—It is not the duty of the medical officer of health to sit in judgment on the accuracy of the diagnosis of the medical attendant who has notified an infectious disease. If he had any good reason for doubt in the matter his duty would be to communicate directly and in a friendly way with the notifying practitioner, on whom the law has placed the responsibility of decision

A CASE OF INTUSSUSCEPTION

To the Editors of THE LANCET

SIRS.—I think it may be worth while to place this case on record as it appears to be an example of a condition referred to in THE LANCET of Oct. 16th 1892, as unusual.

The patient was a male child of Mohammedan parentage aged nine months who was brought to me on Nov. 10th 1892. The illness was said to have begun about noon on the day before—i.e. about twenty-four hours previously the symptoms observed by the mother being a discharge of blood from the anus and a lump in the abdomen. The child had been sick, but how frequently could not be accurately ascer-

MILLER HOSPITAL AND ROYAL KENT DISPENSARY Greenwich road S.E.—Junior Resident Medical Officer for twelve months. Salary £30 per annum with board attendance and washing.

NORTH WEST LONDON HOSPITAL, Kentish Town road.—Resident Medical Officer for six months. Salary £50.

NORTH WEST LONDON HOSPITAL, Kentish Town road.—Assistant Resident Medical Officer for six months. No salary.

PLYMOUTH ROYAL EYE INFIRMARY.—Honorary Surgeon.

ROTHERHAM HOSPITAL AND DISPENSARY.—Assistant House Surgeon, for six months. Rooms common and washing provided in the hospital.

ST PANCRAS AND NORTHERN DISPENSARY, 126, Euston road.—Resident Medical Officer. Salary £100 with residence and attendance. Applications to be sent to the Hon. Sec., 23 Gordon street, Gordon-square W.C.

THE COPPICE Nottingham.—Assistant Medical Officer (unmarried). Salary £120 per annum with furnished apartments, board, washing and attendance.

Births, Marriages and Deaths.

BIRTHS

MCDONALD.—On March 20th at Ebert-street, St. George's road, N.W., the wife of William J. McDonald, L.D.S. Eng., of a daughter.

MANTLE.—On March 27th at Savile place, Halifax, the wife of Alfred Mantle, M.D. of a daughter.

WIGAN.—On March 28th at Portlehead Somerset the wife of Charles A. Wigan M.D., M.R.C.S. of a son prematurely.

MARRIAGES

GREFNE MORRIS.—On April 6th at St. Mary's Church Putney, Henry Bertram B. Greene M.R.C.S. Eng. L.R.C.P.I. of Wandsworth, to Julia Adelaide third daughter of Austin Morris, Esq. Civil Service of Parkfield Putney.

TARGETT-JEFFERY.—On April 5th at Donhead, St. Andrew, Wilts, James Henry Targett M.S., F.R.C.S. of St. Thomas's street, London bridge to Catherine Sarah, third daughter of James Jeffery, Esq., of Donhead.

DEATHS

CRIBB.—On Good Friday at Highbury place, N., Arthur John Cribb M.D. Lond., aged 68.

CROSS.—On the 27th ult. at Madeira, Robert Cross M.D. of Berkeley-square, in his 55th year.

FOX.—On April 4th, in his 46th year, Richard Dacre Fox M.R.C.S., F.R.C.S. late of Manchester.

HAYCOCK.—On the 8th ult. at Clarendon, Crouch hill George Haycock, M.R.C.S. Eng., L.S.A., of No 79 Clarence-road, Clapton, aged 71.

JESSOP.—On the 1st inst., Isabella Harvey wife of T. R. Jessop, F.R.C.S., 32 Park square, Leeds, and Roundhay Mount, Roundhay, aged 63.

READ.—On the 26th ult., at Windsor road Denmark hill, in his 81st year Reginald Read M.D., F.R.C.P. Edin., late of Galford place, Russell square.

N.B.—A fee of 5s. is charged for the Insertion Notices of Births Marriages and Deaths.

NOTICE.—Advertisers are requested to observe that it is contrary to
the Postal Regulations to receive at Post Office letters addressed to
initials only

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on pages 3 and 4, which not only
affords a ready means of finding any notice but is in itself an additional advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.
Answers are now received at this Office by special arrangement, to Advertisements appearing in THE LANCET

Terms for Serial Insertions may be obtained of the Publisher to whom all letters relating to Advertisements or Subscriptions should be
addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's Railway Bookstalls throughout the United Kingdom Advertisements
are also received by them and all other Advertising Agents

tained and no fecal matter had been passed. He appeared also to have abdominal pain at times. The infant was a healthy looking child and did not appear at all collapsed. The face was a little flushed but the temperature was normal. In the left side of the abdomen a tumour could be felt most distinct in the iliac region. One end of it could be just touched by the finger inserted into the rectum but the other end was not distinctly made out. The abdomen was not rigid or distended and there did not appear to be very marked tenderness. I gave chloroform and slowly injected a quantity of warm water into the bowel with a Higginson's syringe the child being at the same time held in a half inverted position, as the sphincter anal was so lax that it was difficult to prevent the water escaping almost as fast as it was injected. By repeated injections the intussusception was gradually reduced the receding tumour being traced in the intervals between them along the descending and transverse portions of the colon. Finally only a small lump apparently about the size of a small walnut, could be felt in the caecal region but one or two further injections distending the whole colon failed to make it disappear. This I supposed to be a small portion of the intussusception which had remained unreduced, and I therefore recommended laparotomy but in spite of endeavours to make them understand the gravity of the case the consent of the parents could not be obtained. They went off to consult with other relatives taking the child with them and I heard nothing more of the case until about a fortnight ago when I was told that he had recovered having no further bad symptoms from the time of the injections. On Feb. 11th I myself saw him alive and well.

I think there can be no doubt that the condition in this case was identical with that described by Mr. Bilton Pollard in THE LANCET of Oct. 15th 1891 although the confirmatory evidence afforded by laparotomy is not forthcoming. The supposition that the small swelling still felt after reduction by injection of water was due to the swollen condition of the ileo caecal valve affords a satisfactory explanation of its persistence when the reduction must have been really complete.

I am, Sirs, yours truly

THE SALE OF MIDWIVES "DIPLOMAS" BY THE OBSTETRICAL SOCIETY AND THE LIVERPOOL LYING IN HOSPITAL.

DR. RENTOU sends us a communication too long for insertion deprecating the sale to women of "diplomas" as he calls them in midwifery observing that the General Medical Council has made a rule to the effect that these diplomas have no legal value. The sale of these diplomas has realised in the case of the Obstetrical Society in the course of eighteen years £935 5s., and in the case of the Liverpool Lying In Hospital £1000 in eight years. What the General Medical Council did was we believe not to "make a rule" but to inform Dr. Rentoul that such certificates are neither licences nor diplomas and possess no legal value, and to point out through the President to the institutions and persons who grant such certificates that the certificates should be expressed in such a form as not to lead to the impression that they are legal qualifications to practise midwifery. It is undoubtedly unsatisfactory that the granting of such certificates should be a sort of business and a source of profit to either societies or individuals who like to take up the work. If the Act of 1893 which required full qualification in medicine surgery and midwifery, is to be tampered with, it should be on conditions and by authorities defined by Parliament.

Inquirer has not enclosed his name and address

SANITARY PRECAUTIONS

To the Editors of THE LANCET

SIRS.—On page 763 of THE LANCET of last week you note the compulsory bath system at Kirkby Stephen. I do not wish to draw inordinate praise upon any of my sanitary authorities, much less on the virtual originator of their action, but I may add that at Kirkby Stephen other means are adopted which you may think worthy of imitation in other districts—viz., all the sleeping rooms occupied by tramps are disinfected during the daytime with chlorine and all the clothing of the tramps is taken from them when they go to sleep and during the night is also exposed to the chlorine fumes for several hours. Whilst revaccination will protect a person who may have been exposed to infection it seems to me absolutely necessary that the farther means of daily disinfection of every item of clothing &c. ought to be carried out for the protection of those who have not been and are not willing to be revaccinated. Another measure adopted is weekly public vaccination in lieu of the usual three weeks in every third month. This is only in the country places of course weekly vaccination in the borough of Kendal being the regular practice at all times of the year.

I am, Sirs, yours truly

Kendal, April 1st, 1893

R. MUSGRAVE CRAVEN, M.O. H.

CLUB PATIENTS AND RAILWAY ACCIDENTS

Surgeon.—The question is a legal one but we should have no hesitation in saying that it is unreasonable to expect the surgeon of a club to attend a club patient for injuries caused by a van belonging to a company, which company has admitted its liability.

THE LIMITATION OF PENALTIES FOR NON-COMPLIANCE WITH THE VACCINATION ACTS

BRIGADE SURGEON ROBERT PRINGLE, M.D., favours us with a communication on the above subject. We are unable from want of space to insert the whole letter, but quote a few sentences, which contain the gist of his contention.

"If Mr. Asquith" says Dr. Pringle "and those who agree with him on the subject of the limitation of penalties for non-compliance with the Vaccination Acts succeed in carrying their point the outcome will be the formation throughout the country of insurance societies for the payment of the single penalty for non-compliance by a small weekly payment for a longer or shorter period according to its amount. The result of this will of necessity be the practical voluntary acceptance of vaccination as the rich will aid in paying the penalty for the very poor who may be unable to meet even a small weekly payment. Here lies the whole secret of this urging of the limitation clause and it therefore seems to me that this will have the effect not only of practically making this acceptance voluntary but doing it in a manner which forfeits the only justifiable plea for the infliction of any penalty for non-compliance, and doing it by means of what is really a legal evasion obtainable by a fixed payment. If compulsory vaccination is necessary the public health there should be no means of evading it, and certainly no legal ones. If vaccination can be shown to be either not necessary or only so at a cost of risk of injury to health out of proportion to the supposed benefit then let compulsion be abandoned and the acceptance of the prophylactic made voluntary and the country take the consequences."

Mr. Edgar Waelly should consult the Medical Directory

HYPERPIREXIA IN A CASE OF INFLUENZA.

To the Editors of THE LANCET

SIRS.—The following case strikes me as being of some interest on account of such an astonishingly high temperature—

A plasterer was taken ill with pains in his limbs, back and head on Monday, March 13th. I saw him the same day, and found him suffering from influenza his temperature being at that time 103° F. It never rose above this (and dropped on two or three occasions to 101° F.) until the Monday following (March 20th). I was called to him at 3 A.M. when I found him quite insensible with very pronounced stertorous breathing and on taking his temperature I was extremely astonished to find it registered 108° F. On touching his skin it was so hot that I could barely keep the back of my hand on it. I immediately ordered him to be sponged all over with cold water, but he succumbed in less than half an hour. His wife informed me he had spoken quite sensibly to her at 2 A.M. and had taken some milk. I had carefully examined him throughout his illness for any lung cardiac or cerebral trouble but could discover nothing amiss. It might be suggested that my thermometer was wrong. I can only say I had quite recently tested it with several others and have done so since, but find it to be correct.

I am, Sirs, yours faithfully,

W. H. BOGER M.R.C.S. Eng., L.R.C.P. Edin.

Fowey Cornwall March 26th 1893

METEOROLOGY

THE Weather Conference which is to take place at Chicago in the autumn may or may not result in the formulation of data by which forthcoming weather may be safely predicted. A little pamphlet, written by Mr. Hugh Clements sets forth a plan by which this desirable end may be attained. In view of the very moderate amount of success achieved up to the present time by experts on meteorology, it is excusable not to indulge in extravagant hopes in the practical outcome of the Conference or in the efficacy of the scheme propounded by the writer referred to.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

During the week marked copies of the following newspapers have been received—Leicester Daily Mercury, Western Daily News, Blackburn Daily Telegraph, Pontefract Express, Lancashire Evening Express, Cork Constitution, Oban Telegraph, Cheshire Evening Echo, Morpeth Herald, Louth and North Lincolnshire Advertiser, Liverpool Courier, North Eastern Daily Gazette, Poole Herald, Yorkshire Post, Jersey Observer, Coltridg's Express, Birmingham Gazette, Kentish Mercury, Bristol Times, Liverpool Daily Post, Bristol Mercury, Glasgow Herald, Stafford Evening Post, Dundee Courier, Wolverhampton Chronicle, Leeds Mercury, Reading Mercury, Mining Journal, The Morning Weekly Free Press and Aberdeen Herald, Public Health West Middlesex Standard, Surrey Advertiser, Local Government Chronicle, Hertfordshire Mercury, Metropolitan Journal, Scottish Leader, Cape Argus, Sunday Times, Builder, Architect, Observer, Sunday Chronicle (Manchester), Waterford Chronicle, Citizen, West Middlesex Advertiser, Leith Burghs Pilot, Scotsman, Indian Daily News, Pioneer Mail, Fraserburgh Advertiser, Times of India.

ver and diarrhoea, when they are prevalent at Chicago, prevail chiefly in those parts of the city which abut upon its noxious branch of the Chicago River.

The Lake at the time when our samples were drawn was free from chemical evidence of sewage pollution to an extent that, regard being had to the amount of sewage which in one form or another it receives is surprising. In connexion with this result it must be borne in mind that the season was peculiarly favourable to the purity of the Lake water. For some weeks before Dec. 10th the weather had been tempestuous, and it was only by seizing a favourable opportunity that the tug employed by our agent was able to get out upon the Lake. It may be taken for granted, therefore, that dredging operations had been suspended for some time, at least so far as dumping the sludge in the Lake is concerned. Still, when all due allowance is made for this circumstance, it is as we have said, a surprising fact that water taken from the Lake over the dumping grounds was of a quality save for its suspended matter, superior to that of the ordinary London water-supply—that is to say, the percentage of dissolved matter of organic origin was less than in the London waters, and as the suspended matter could all be removed by effective filtration it is plain that even at this point the Lake, under favourable conditions will supply water which wants nothing but the most ordinary treatment to render it fit for any and every domestic purpose. It is a result of our labours upon which we congratulate the people of Chicago most cordially and with the liveliest satisfaction that they have thus demonstrated the possession by the city of an illimitable water supply which needs nothing but good management to render it all that could be desired.

In one way this great boon has proved a bane to the people of Chicago, for, having so superabundant a supply of water ready to hand, they have—naturally enough, perhaps—used it as they found it, and consequently their very extensive water-works are designed with the view simply of pumping and in no way of treating by filtration, the water of the Lake. Unfiltered, this water is quite unfit for drinking by reason, as we have pointed out, of its suspended matter, hence the security of Chicago against a serious outbreak of epidemic disease depends entirely on the care with which the water is purified before use by means of domestic filters. This is the weak spot in the city's armour, and to this we desire in the most effective manner possible to draw the serious attention both of the citizens and of the urban authorities. The matter is one of capital importance to visitors to the city, it is of equal importance and of even more permanent concern to those who dwell there. Now it will be found on reference to the chemical report that our specimens have included two samples of filtered Lake-water. These samples should have been beyond reproach. Both had been treated by the Pasteur filter, and yet both were found to contain suspended matter in great abundance, so that neither could be trusted to be free from dangerous impurities. The explanation of this seeming anomaly is perfectly simple. *The filtered water had in both cases been cooled by the admixture of polluted ice.* No words are necessary to prove that this is a foolish and most mischievous practice. It manifestly renders the filtration wholly futile. Yet we are informed that it is common, even to the point of being almost universal, throughout the United States, but with any widespread custom we are not now concerned. Our attention is claimed by the city of Chicago and here during the present year the practice will involve the most formidable risk. The presence of a vast concourse of people drawn from every quarter of the globe is obviously a condition of things which calls for the adoption of special sanitary measures, and nothing whatever could be more plainly or more impudently demanded by the circumstances of the case than safe methods of treating the drinking-water. The general use of filters in the hotels and restaurants of Chicago is therefore, a necessary safeguard, but it is no safeguard at all if contaminated ice be permitted to dissolve in the filtered water.

It may seem perhaps that we are bestowing excessive labour upon an obvious point in thus insisting upon and reiterating a precaution which nobody will be found to deny, but it is a practical and not a merely logical aim that we have in view in writing thus. Our inquiry has brought to light a practice fraught with peril at any time and capable at the present moment of breeding mischief on an appalling scale. If this can be proved to be untrue and a better system introduced nothing more must be done than to demonstrate, however clearly, that the system complained of is inconceivably bad, and to point out, however instructively the simple and obvious

remedy of using two receptacles placed one within the other for the cooling ice and the drinking water respectively, so that they may not mix their contents or pass anything but heat from the one to the other. So much is easy enough, the difficult task is to make people understand and feel of how weighty significance such clear and simple statements are. For ourselves, we are so impressed with the importance of this point that we shall esteem the trouble and expense which we have undertaken in the prosecution of this inquiry to have been excellently well bestowed if, as the result of all, we can convey to our American hosts an adequate sense of the issues both to them and to us which are involved in the careful avoidance of this one channel of infection. The researches of which we to-day publish the results have brought to light a great number of points of first-class interest and importance to which, in this summary review we have so far made no allusion, but imperfect as this survey is, we prefer to leave it so, rather than to weaken, by passing to another topic, the effect of these observations upon the dangers of the contamination of drinking water by means of cooling ice. In other respects our examination of the facts has led to what is, upon the whole, a reassuring result, but we cannot feel free from very serious misgiving until we are reassured upon this point also, for the statistics of mortality show that Chicago suffered from typhoid fever nearly eight times as much as London in 1890 and nearly twelve times as much as London in 1891. To our own people we commend in the strongest terms the advice to *drink no water which has been cooled in contact with ice*, to the people of Chicago we appeal to provide a supply of water free from this reproach.

COURSE OF THE INQUIRY

In an article devoted to the subject of the inquiry of which the results are collected in the following pages we have explained the circumstances which led us to undertake the task. The results are fully set forth in the technical chapter which follows this, and which contains the reports drawn up by the chemists who have conducted the analyses of the lake, river and domestic supply waters. It will be interesting and indeed not unimportant to recount here, by way of introduction to that report, the steps by which the work has proceeded, in order that the true significance and value of the result itself may be ascertainable by those of our readers who may be interested to examine it in detail.

The first step taken, when the task had been resolved upon, was to obtain the fullest available information concerning the systems of drainage and water supply. The principal sources from which this information was collected were the Mayor's messages for the years 1890 and 1891. In these documents a very large amount of information was to be found, which we were able to supplement in a few particulars from less authoritative sources, and here it is only just to observe that, although unofficial sources of information are singularly meagre, we have found the city authorities exceedingly courteous in dealing with our inquiries and on all occasions most ready to give the information asked for. Except that most of it has come to hand in a somewhat fragmentary and disconnected form we have therefore experienced no trouble beyond that of asking questions in a distant place in the acquisition of such materials as were necessary for our purpose.

The raw material so obtained was placed in the hands of a member of our staff and from it he compiled a connected account of the general schemes of drainage and water supply which was furnished to the chemists by way of explanation of the specimens of the water which had been in the meantime analysed by them, and in this way it became a part of the materials upon which their report was based. At the same time a proof of this statement was forwarded to the Mayor of Chicago with an explanation of the objects aimed at in the inquiry and of the steps taken to secure its efficiency. He was asked to give the paper his attention and to favour us with his criticism upon it should he find it to be in any respect inaccurate and to bring to our knowledge any matters omitted therefrom which might appear to him necessary or proper to be considered in this connexion. The Mayor replied that he would cause an exact report of the drainage system and the water supply of the city to be prepared and furnished to us a promise which was duly redeemed a fortnight later. The official statement so furnished by the Mayor of Chicago has been given in this report as received from him in the form of letters from the several city authorities (city engineer and medical officer of health),

REPORT OF

THE LANCET

SPECIAL SANITARY COMMISSION OF INQUIRY

CONCERNING THE

WATER-SUPPLY OF CHICAGO, U.S.A.

THE city of Chicago has, speaking roughly, two outlets for its sewage matters—Lake Michigan and the Mississippi River—and one source of water supply—Lake Michigan. The Chicago River, which serves as main sewer to the city, flows naturally into the lake, but in order that its burden of sewage matters may not be all discharged there a powerful pumping station has been erected some distance up the stream on its southern branch. From this point the river water is pumped over a lock into a canal which carries it far south into the Missouri and eventually into the Mississippi River. The bulk of the liquid sewage is disposed of in this way. Several sewers serving the Lake shore districts of the city debouch upon the lake, but their aggregate output is estimated at less than 15 per cent. of the total sewage of the city. Subject to this abatement the Missouri and Michigan Canal receives as its quota of the whole discharge the liquid, dissolved and floating matters. The suspended matter which deposits as sludge on the river bottom is removed by dredging and carried out to the lake, which thus receives these solid matters in addition to the Lake shore sewers' discharge as its proportion of the city's drainage.

The water supplied for domestic and other use within the city is, as already stated, drawn from the Lake, and is conveyed to the pumping stations, which are distributed at various points throughout the city, by subterranean aqueducts extending for distances which vary from one to four miles under the bottom of the lake. The water is thus taken from points lying at various but no great distances from the sources of pollution, and chosen with regard to the observed effect which the sewers produce upon the condition of the Lake water. The water so obtained is pumped into the city mains and undergoes no filtration or other treatment until it is delivered in the consumer's house, save such as may result from the mixing of atmospheric air with it in the pumping operation and the deposition of some greater or lesser proportion of its suspended matters in the conduits through which it flows.

In addition to the water of the Lake, waters from three other sources of supply have been examined in the course of this inquiry. These are (1) the water of the Washington Heights artesian well, a source of supply for a limited district within the city which need not be considered in this place, and (2) and (3) the waters from the "Hygeia" and "Silurian" wells at Waukegan—spring waters which are largely consumed for drinking purposes within the city and of which the first named, "Hygeia" water, is by means of a special pipe to be brought in large quantities and distributed at a charge of one cent (one halfpenny) a glass throughout the World's Fair grounds. For the preparation of lake water for drinking the use of domestic filters is very common in Chicago, and may be said to be universal in the hotels, the form of filter most in favour being that known by the name of Pasteur—in design a very excellent instrument and one which, so long as it remains undamaged by fracture or displacement of its parts, may be relied upon to do its work efficiently.

Such in bare outline are the conditions under which water is supplied to Chicago. Those of our readers who may be interested to examine these facts more carefully will find them

detailed in the technical portions of the report of this Commission. We now proceed to deal here with the results to which the chemical examination has led. It will of course be understood that the chemical examination of water deals only with the question of pollution, not with that of infection. A water that is chemically of very high character in respect of purity may by chance be seriously infected with disease germs, and, on the other hand, a water which is extremely foul may be absolutely free from the seeds of specific disease. This question can only be positively answered by bacteriological examination and by the study of the effects of the water on those who drink it. No such bacteriological examination has been practicable in the present case, because of the length of time necessarily consumed in transporting the specimens from Chicago to London. The period so occupied would have sufficed for the occurrence of most important changes in the conditions of bacterial life upon which such an examination must proceed. The value of chemical analysis is chiefly due to its affording a very substantial ground of inference. Typhoid fever, cholera and diarrhoea are the principal disorders which are disseminated by sewage contaminated water, and in practice water receives such germs from sewage only. If, therefore, sewage contamination can be detected by any means, it is certain that the contaminated water is unsafe for drinking purposes, however innocent the actual sewage matter discovered may itself be, for the vehicle which conveys innocuous sewage to day may convey pernicious germs to-morrow. A water which is chemically impure, if the impurity be traceable to sewage contamination, must be an object of distrust, so also must a water which is excrementally polluted, even if chemical analysis fails to show evidence of this pollution. It is to the determination of the sewage derived constituents that the labours of Mr Crookes and of our own analyst have been chiefly directed and their detailed technical report has settled the rank in the order of purity of every one of the specimens of water subjected by them to analysis. For the citizens of Chicago and for anybody else who is interested in the elaboration of the large schemes of sewerage and water supply which must sooner or later be undertaken by the great and growing city, their report will possess a permanent interest, and will be of greatest interest precisely in those passages which are chiefly of theoretical significance—in those, for example, which deal with the condition of the Chicago River and the Lake dumping grounds. These, from our present point of view, may be summed in a very few words. The river is shown to have distinct characters in four different parts of its course. In the North branch it is satisfactorily pure and perfectly sweet water. In the Southern branch it shows increasing pollution as one travels back from the mouth towards the source, and in the branch which turns away towards the stockyards and lies apart from the main current of the river filth has accumulated to an extent which has converted the water into a material more offensive than the untreated outpourings of an ordinary sewer. And as the river is at this point, it is, however, unnecessary to warn visitors against frequenting its neighbourhood, for the simple reason that the stench of it is warning enough and no ordinary traveller through those parts is at all likely to approach the river unwittingly or to seek its precincts as a matter of choice. It is not at all surprising to find that typhoid

The thermometers used for this purpose were afterwards examined in THE LANCET Laboratory and their readings compared with a standard thermometer. They were found to be correct to within half a degree.

MAP I, SHOWING COLLECTION OF SAMPLES

EXPLANATION.—The numbers enclosed in circles represent samples lost in transit.

1. Chicago River at Putnam and Roberts Bridge. (This sample was lost in transit.)
2. Ditto at junction of north and south branches
3. Ditto between Wabash and Rush streets
4. Ditto at Union Depot.
5. Ditto at Dupont's Slip
6. Ditto at Fuller and Kost streets
7. A. Canal.
8. Chicago River abreast of Joliet steel works
9. Lake Michigan two miles out (These samples were lost in transit.)
10. " " near four mile intake (This sample was lost in transit.)
- 11, 12, 13 and 14. These were all samples of drinking water taken in different parts of the city, not shown on map (They were all lost in transit.)
- 15 and 16. These numbers were not used to designate samples at all.
17. Chicago River just below Fullerton Avenue.
18. Ditto half a mile above Fullerton Avenue
19. Chicago River two miles above Canal pumping works.
20. Ditto East Fork, close to stockyards
21. Canal near pumping station
22. Lake Michigan. Taken over dumping ground. Deep sample (12 feet).
23. Lake Michigan. Taken over dumping ground. Surface sample
- X. Fullerton Avenue pumping station for flushing north branch of river (Marked x on Map II.)
- Y. Canal pumping station for reversing current in river (Marked y on Map II.)

It will be noted on inspection of the table below (Table I) that the temperatures all through were low, indeed in some instances the water was but a shade above freezing point. Further than this, it so happened that cold weather prevailed throughout the journey of the bottles from the time of collection at Chicago to the day the samples were received at THE LANCET Laboratory. It is safe to assume, therefore, that little or no change in the composition of the water could have taken place.

OPERATIONS IN THE LABORATORY

The complete analysis of one sample was in each instance carried out before analytical operations were commenced with a second, so that the results might not be affected by

changes which, on the withdrawal of the stopper, might take place through exposure to air. In samples containing sulphuretted hydrogen the gas was estimated immediately on opening, a precaution the necessity of which was obvious from the fact that it gradually diminished in quantity and finally was absent altogether as indicated by loss of smell. Suspended matter was also immediately determined, as its character in some instances was observed to alter rapidly from the same cause. For this purpose a porcelain crucible with a perforated bottom, covered with asbestos wool, was employed. By this arrangement not only was the total amount of matter in suspension determined, but also the matter volatile on ignition (organic) and that which was fixed (mineral) were ascertained. In all other analytical operations the clear water was used.

With respect to colour determination, the ratios expressed in Table I below show the proportion of brown to blue in the water, the figures representing millimetres in thickness of the respective standard solutions. Thus 8 20 would express a colour composed of 8 millimetres of standard brown solution, superposed on 20 millimetres of standard blue solution (the normal colour of pure water). The organic carbon and nitrogen were determined by the excellent and accurate though somewhat tedious combustion process of Frankland. It consists briefly, first, in the evaporation of the water to dryness, either with sulphurous acid or phosphoric acid, according to the nature of the water, to fix the free ammonia present and to destroy the carbonates, nitrates and nitrites. The residue so obtained is then mixed with perfectly pure oxide of copper and burnt *in vacuo*. The carbon is thus obtained as carbonic acid gas and the nitrogen in the elementary form. By means of the Sprengel pump, these gases are pumped into a suitable tube and afterwards transferred to a gas analysis apparatus for analysis and measurement.

This process, it may be mentioned, was found to yield excellent results when a liquid containing a known amount of carbon and nitrogen was experimented with. The liquid so used contained an accurately weighed quantity of pure caffeine so that a thousand parts of the liquid were equivalent to 0.040 part of carbon and 0.023 part of nitrogen. The figures actually obtained in an experiment carried out on the lines just indicated were C, 0.044, N, 0.0225.

The free ammonia was determined in a few instances by distilling a known quantity of the water into acid of definite strength. In other cases the usual process of Nesslerizing the distillate was adopted. The total solid matter in solution was obtained by simply evaporating a given volume of the water to dryness, the hardness was found by the effect produced on soap solution of definite strength. The oxygen required was determined by means of an acidified solution of potassium permanganate acting in the cold for fifteen minutes and for three hours. The former result is taken to indicate the extent of very readily oxidisable substances—sulphuretted hydrogen, ferrous salts, nitrites, and probably some organic matter, and the latter obtained after deducting the former to indicate organic matter only.

The chlorine was estimated by means of a standard silver solution, the results obtained are calculated into the equivalent of common salt, 100 parts of which contain 60.7 parts of chlorine. Nitrogen, when it occurred as nitrate, was determined by means of phenol sulphonic acid, which is converted by any nitrate present in the water into picric acid and subsequently into yellow ammonium picrate on treatment with ammonia. The yellow colour so produced was compared with a solution of nitrate of known strength similarly treated. Nitrogen existing as nitrite was detected by means of the very delicate reaction taking place between the product of the action of nitrous acid upon sulphamic acid and amido naphthalene. A salmon pink colour due to formation of an azo-compound is produced. Lastly, the microscopic examination of the sediment was made, the results are recorded in Table II.

Having thus touched briefly upon the salient points in the analyses conducted, the results actually obtained (see Table I) may now be considered. They are expressed in all instances in grains per gallons.

REMARKS ON TABLE I

A close inspection of Table I leads to the division of the waters there enumerated into four characteristic groups.

I. Water excessively and grossly fouled with sewage and other animal matter.

II. Water decidedly polluted.

III. Water still polluted, but to a less extent.

IV. Water generally of good quality and organically pure.

and our own statement, revised and completed in the light of this communication, appears in the present context as Appendix I.

Whilst the work of collecting information was thus going on in one department, that of collecting samples of water for analysis was going on in another. For this duty the services of Mr. Frederic Myer, a journalist residing in Chicago, had been secured in the manner to which allusion has already been made in the earlier narrative. In order that there might be no mistake about the provision of suitable bottles and packing cases, these were attended to in London, and early in November last two packing cases, prepared and fitted by Messrs. Baird and Tatlock, were despatched to our agent in Chicago containing each a dozen bottles, all of which had been carefully washed, sterilised and stoppered and capped with parchment before being sent. The parchment caps were secured with THE LANCET seal and so business like did these empty bottles appear that the Custom House examiner at Chicago sent for the consignee and demanded of him what kind of gas he was importing into the United States. It seems that the McKinley tariff had not imposed a duty upon London atmosphere even when bottled, and so the bottles passed in with contents duty free. The bottles were accompanied by a piece of apparatus to be used in sinking and filling them and also by minute directions for their manipulation in this operation. These are fully explained in Appendix III to the present report.

So equipped, our agent set out upon the expedition. For this purpose he hired a steam tug and spent a day in what we do not doubt he quite accurately describes as very arduous work on the lake and the river. Stormy weather and other adverse circumstances prevented him from carrying out this operation until Dec. 10th last. How it was then carried out may best be seen in his own report and in the log of the expedition, both of which appear in Appendix III. On Dec. 14th the two packing cases left Chicago on their return journey, and on Dec. 21st they left New York for Liverpool on board the steamship *Germania*. Even then the troubles of the journey were only beginning, for, by a most extraordinary blunder, one of the cases, instead of being delivered at Liverpool and forwarded in due course to London, was sent back on board the *Germania* to New York, and only arrived a month later when the *Germania* returned from this second voyage. It had then been exposed to the cold wave which visited New York about the middle of January, and probably from this cause eight out of ten sample bottles which it contained had suffered fracture. The companion case, which came through in due course, reached us in perfect order, with all its samples intact and with unbroken seals, showing that they had reached THE LANCET Offices in precisely the same condition as that in which they left the hands of our agent at Chicago.

As soon as it was known that the samples of water had been obtained and were on their way from New York, arrangements for the chemical analysis were put in hand. We desired to obtain for this task the services of chemists whose skill and reputation would secure for their work unhesitating acceptance on both sides of the Atlantic, and therefore in the first instance we proposed to appoint a commission of three chemists and invited the American Minister in Great Britain to nominate one, the Royal Commission for the British Department of the Chicago Exhibition to nominate a second, reserving for our own analyst the third place. It was understood that if the American Minister consented to make such a nomination the Royal Commission would do likewise, but the former explained that it was a matter in which he did not feel himself authorised to act as desired, and intimated that the Mayor of Chicago would be the proper person to receive any such invitation. As it was manifestly impossible to hold the necessary communications with the Mayor of Chicago in the time at our disposal this proposal broke down completely and nothing whatever resulted from it.

It thus became necessary for us to fall back upon our own resources, and went once applied to Mr. Wm. Crookes, F.R.S., and requested him to undertake, in consultation with our own analyst, the work of analysing and reporting upon the samples of water obtained. This he very kindly consented to do, and the whole of this work has been carried out with his advice and assistance. THE LANCET Laboratory was specially fitted up for the duty and the arrangements were inspected and approved by Mr. Crookes. In like manner the Laboratory was visited by him from time to time whilst the work was in progress and he was provided with a duplicate of every sample which was there analysed. The

routine was to divide the contents of every bottle as it was opened into two portions—one was taken away by Mr. Crookes for independent control analysis, and the other was operated upon in our own Laboratory. It is not uninteresting as an example of the precision of modern chemical methods to remark that in the determination of chlorine, which was selected by Mr. Crookes as the standard test experiment, the series of figures given in Table I, and independently obtained, first in THE LANCET Laboratory and afterwards in Mr. Crookes' laboratory, were found to be in agreement to the second place of decimals. Now, as these results are expressed in grains per gallon, the effect of that statement is that the two analyses yielded results which agreed to *one part in seven millions*. It is as if two surveyors measuring a distance of 100 miles were to obtain the same result to a single inch, and were to repeat the operation fourteen different times in as many different places, always with the same startling coincidence of results.

The packing case which suffered so severely on the journey from New York contained all the specimens of drinking water at first obtained. These were all lost. Telegraphic instructions were immediately despatched to our agent to replace them, and this he proceeded to do, providing on this occasion his own bottles as time did not serve for sending out a fresh supply from this country. Such a precaution was indeed unnecessary, as he was already experienced in the work of bottling the samples and the taking of drinking water of course presented no difficulty. In one respect only did the treatment of these later samples differ from that of the earlier, that is to say, the bottles were stoppered with cork instead of glass. There seems, however, no reason to doubt that the corks were perfectly sound and effective stoppers, and, indeed, if any contamination had been occasioned in this way it would certainly have been made evident by a comparison of the domestic supply waters with the lake water samples (9, 9a and 10 of the first series). The comparison is, in fact, entirely satisfactory, and the analysis of the domestic supply waters is as worthy of trust as that of the first series of samples. The samples of the second series are numbered from 25 to 36 on the accompanying report and are not indicated on the map as they have no topographical relations properly so called.

CHEMICAL REPORT

The collection of samples was as has been already explained, entrusted to a specially appointed agent in Chicago, who was supplied from London with all necessary apparatus and instructions. The bottles selected for this purpose were of green transparent glass of 80 ounce capacity (the Winchester quart) and well stoppered. They were thoroughly cleansed and air dried, and the stoppers tied on with parchment and sealed with THE LANCET seal before being packed in the case. Every precaution was taken to ensure the contents of the case against damage. To this end each bottle was made to fit in a box lined with baize and padded with cotton wool. The lid was also fitted with padding in which the stopper neck and shoulder of the bottle were firmly embedded. The boxes were perfectly square, and twelve of them fitted exactly into an inner case. The inner case was closed with a lid by means of screws. The outer case into which it was placed was provided, as was also the lid, with rubber buffers to prevent shaking. The outer case was firmly screwed down and the corners protected with metal caps. Two cases so furnished were despatched direct from THE LANCET Laboratory to our agent at Chicago, who was instructed to carry out the following directions respecting the collection of the samples—

It is desired that samples may be collected at the various spots herein indicated. The letters (longitudinal lines) and figures (latitudinal lines) refer to the large scale map of Chicago in our keeping; a copy of which you also have.

[Here followed a specification of selected spots, which need not be repeated as the localities chosen were practically identical with those shown on Map I and enumerated in the log of the expedition.]

The temperature of the water and that of the air should be determined at each sampling station, and observations like the direction of wind, character of odour, rate of current, turbidity, nature of surroundings, recent disturbances by shipping &c., should be accurately noted, together with other information which appears to be of importance for the purposes of the present investigation.

It may be mentioned that one of the cases was further provided with a compartment in which was contained the apparatus necessary for the convenient collection of the river and lake samples. This apparatus is described and figured in Appendix III, p. 847.

To Group I belong the samples 19, 20 and 8. The district from which they were derived is distinguished by full black on the accompanying diagram.

To Group II. belong Samples 6 and 7 and the district from which they were obtained is marked by dark shading on the same diagram.

To Group III. belong samples 2, 4, 5 and 21, coming from the part of the river distinguished by light shading.

Lastly, to Group IV belong the samples 3, 17, 10, 22 and 23, the last three being lake samples. The districts from which the river samples were taken are indicated on the diagram by plain outlines.

Table III. giving the average composition of the members of each group, shows at a glance the chief variations in the analytical results obtained.

It is convenient to consider and discuss the groups *seriatim* and the individual members in each.

DIAGRAM SHOWING CONDITION OF CHICAGO RIVER.

EXPLANATION.—The plain outlines show unobjectionable water (Group IV). The light shading shows water unmistakably contaminated (Group III). The dark shading water very much contaminated (Group II). The full black, filthy water—very bad sewage (Group I). The numbers are derived from Map I. and refer to the samples of river water obtained for analysis as explained in connexion with that map.

Group I.—Words could hardly describe the filthy description of the samples belonging to this group. The observations made by our agent in this connexion at the time of collecting the samples and given in Appendix III. are of interest. That very little change had taken place in these samples during their journey to THE LANCET Laboratory was pretty evident from the fact that his observations with respect to the colour and smell of the samples were fully confirmed when they were submitted to analysis. They all emitted the disgusting odour of sulphuretted hydrogen—in fact on removing the stoppers from the bottles bubbles of gas were seen to escape. On removing the smell of sulphuretted hydrogen by the addition of a solution of iodine to the water the residual smell was even of a more disgusting type, resembling very closely accompanying fecal matter. During the evaporation of the residue for the estimation of the total solid matter

a sickening smell, partly resembling bad glue and partly sewage, pervaded the atmosphere of the laboratory.

A noteworthy feature in the waters of this group, as will be seen from Table III, is the excessive amount of ammonia contained in them, with a corresponding quantity of organic carbon and nitrogen, the relation of these elements indicating excessive pollution with animal matters. This is again confirmed by the enormous amount of chlorine, which calculated

TABLE II
Microscopical Examination of Sediment (River and Lake)

Sample No.	Observations
2	Swarming with bacteria, diatoms, parameria, monads and other moving organisms.
3	Bacteria, desmids &c., and silicious matter
4	Plant products bacteria, silica and iron.
5	Several groups of bacteria, monads iron and other mineral matter
6	Animal hairs bacteria, plant tissue in abundance.
7	Bacteria, monads mineral deposits and animal debris.
8	Teeming with bacteria and bacteria fronds, mineral debris &c.
10	Several bacteria desmids and mineral matter
17	Few bacteria diatoms, desmids and plant debris.
19	Several bacteria, mineral matter and plant debris.
20	Bacteria in abundance in well defined rod like chains mineral matter &c.
21	Plenty of bacteria desmids and mineral matter
22	Few organisms plant and mineral debris.
23	Bacteria protozoa and plant debris.

The numbers in this table represent the same samples as in Table I.

TABLE III.

* Insignificant.

opening of the samples of this group till the water at last became quite opaque. This is not to be wondered at when, as analysis shows, the waters abound not only in nitrogenous matter but also in phosphates. The waters of this group, in fact, would serve as an excellent culture medium for the growth of organisms so abundantly does pabulum exist. The amount of phosphates is simply phenomenal on testing each sample in the group as it stood it was found to give an abundant precipitate with ammonium molybdate solution.

Group II.—In the samples of Group II the kind of pollution is precisely the same—that is to say it is mainly of animal origin, but the constituents which represent this contamination are smaller in quantity. Thus the salt is reduced to 9.24 grains, the sulphuretted hydrogen to 0.46 grain, the suspended matter to 9.80 grains, the ammonia to 1.25 grains and the carbon and nitrogen to 1.34 grains and 0.433 grain per gallon respectively.

The observations of our agent at the time of collecting the samples are in accordance with these results. The smell emanating from the samples on opening in the laboratory was objectionable enough, and on evaporation of the waters the disgusting smell of stale sewage was unmistakable. Phosphates were again found in abundance, whilst microscopical examination showed in No. 7 plenty of bacteria, weeds and silicious matter and in No. 6 vegetable debris, animal hairs, low forms of vegetable life and earthy matter. The character of the suspended matter was similar to that contained in Group I. It was black and evolved a disagreeable smell on ignition, and the incinerated residue was brown from the presence of iron.

Group III.—Of the members of this group, No. 21, from the canal off Bridgeport was decidedly the worst. It contained 0.93 grain of sulphuretted hydrogen, whilst No. 5 contained 0.71 and Nos. 2 and 4 only traces. Similar ranges in the quantity of ammonia and chlorine are noticeable.

Unmistakable as the contamination of these waters is it will be observed that the individual constituents which indicate pollution occur again to a less extent than in the preceding group. The suspended matter in the waters of this group was less in quantity but of the same kind. It evolved a disagreeable smell on burning and left a residue containing iron. The sulphuretted hydrogen smell of these waters was less strong, but on evaporation of the samples to dryness the same disgusting sewage odour was noticeable.

Nitrates it is interesting to note, occur for the first time to any measurable extent in this group, the amount averaging 0.63 grain calculated as nitric acid, and in one member (the carbonate of the whole series) nitrates were detected. Phosphates, best remarked again abound, and microscopical examination of the sediment showed a similarity in the samples. Thus in No. 2 swarms of bacteria were found, as well as monads and an excellent specimen of diatom, in Nos. 3 and 4 plant debris and bacteria, in No. 5 swarms of bacteria monads paramoecia, and in No. 21 bacteria, plant debris and mineral matter.

Group IV.—This group is sharply distinguished from the rest by a sudden drop not only in the amount of the constituents which are indicative of animal contamination, but also in constituents of a mineral character. Thus the ammonia dwindles to a mere trace, the organic carbon and nitrogen also diminish considerably, whilst there is a corresponding increase in the amount of nitrogen in the form of nitrate. These waters are less hard contain much less chlorine, absolutely no sulphuretted hydrogen, and the oxygen abstracted from permanganate of potassium was practically nil, from which it may be concluded that organic matters are almost entirely absent. The organic nitrogen of No. 3, it should be pointed out is somewhat higher than the others, and on this account would give rise to some little suspicion. It is suggestive, too that of the five members included in this group it was No. 3 that contained a measurable quantity of suspended matter (vide Table I.) Nos. 10 and 17 contained a slight sediment only. In addition to this water fleas were seen swimming about with the exception of No. 10 which was a sample taken in the lake four miles out. A reference to Table I. will show that three of the members of this group Nos. 10, 22 and 23, were taken from the lake, and the remaining two Nos. 3 and 17, were taken from the river at points where either the lake water has free access or is pumped in. A few bacteria, monads, desmids, procoeca, regular pond water organisms, water weeds &c. were discovered in the sediment of the members of this group. Phosphates were still present in this group, though less marked.

OBSERVATIONS AND DEDUCTIONS ON THE FOREGOING RESULTS

The foregoing results lead to some interesting inferences. Let the forms under which nitrogen is generally found in waters first be considered. Nitrogen may exist in organic matter, in ammonia, or in nitrates and nitrites. When it is present as organic nitrogen in the water present pollution with objectionable matter of some kind, generally sewage, is indicated, if it is present as ammonia, present and recent pollution may be indicated, but if present in nitrates in the absence of ammonia and organic nitrogenous matter then the pollution is probably an event of the past. Organic matter in fact by the natural purifying actions of the air, of the air dissolved in water, aided by specific organisms rapidly changes into ammonia and eventually into the complete oxidation product, nitric acid or nitrate (bases being present sufficient to neutralize the acid formed). When, however, nitrites are present, both past and present contamination with organic matter is indicated, for nitrites are known to be formed from the reduction of nitrates by organic matter. It is probable therefore that water containing nitrites as well as nitrates has been and is being contaminated. On inspection of Table III it will be found that both nitrates and nitrites are absent from those waters containing an excess of organic matter and of nitrogen. On the other hand, waters containing traces of ammonia, or no ammonia at all, invariably contain nitrates. This lends support to the views just expressed. The water containing most nitrate is No. 17, and this is a sample of water it is interesting to note, which was taken from the Chicago River below Fullerton avenue, just where water is pumped into the river from the lake. The presence of nitrates may there be accounted for by the action of the fresh aerated water of the lake upon the nitrogen contained in the organic matter, or the nitrogen existing in the river as ammonia above this point. Sample No. 3 illustrates again the oxidation of nitrogen taking place. This was obtained near the mouth of the Chicago River—that is to say, where the river water is most likely in contact with or has access to the lake water. The nitrogen as nitric acid amounts to 0.315, whilst as to nitrogen as ammonia, there is none. Traces of nitrates occur also in Samples 10, 22, 23 and 4 and existing pollution is indicated again by the presence of nitrites in No. 21. The entire absence of nitrates in waters containing sulphuretted hydrogen is noteworthy, reduction rather than oxidation being of course indicated.

Now, turning to the chlorine contained in the water, it will be seen that it varies as the ammonia. The presence of large quantities of chlorine may afford evidence of both past and present contamination unless the source of the supply is in close proximity to the sea. Sewage contains on an average seven to eight grains of chlorine per gallon. Inasmuch as the water supply of Chicago—that is, the water of Lake Michigan—does not normally contain according to these analyses more than 0.66 grains per gallon any quantity found in the water supply greatly in excess of that amount would naturally arouse suspicion. Attention might also be drawn at this point to the somewhat remarkable occurrence of phosphates to a more or less extent in all the samples. Phosphates are a normal constituent of course, of animal matter but they also occur abundantly distributed by nature in mineral deposits. We have no evidence whether Lake Michigan contains phosphates normally or not but the enormous amount of phosphates in the Chicago River especially near the stockyards points to pollution with animal excreta, at any rate the presence of phosphates in drinking water is not desirable, inasmuch as they minister to the growth of organisms.

The initial hardness of the waters would appear to vary directly with the extent of organic pollution, a fact which is probably due to the use of lime salts in many unwholesome industries. The lake water possesses eight degrees of hardness which is tantamount to saying that it contains eight grains of chalk per gallon, it possesses a hardness in fact less than half of that of London water.

Next may be noticed the variations in the amount of oxygen absorbed. The river water absorbed large amounts of oxygen consistently with the large amount of organic matter present. Samples from the lake absorbed little or none. The oxygen absorbed by a deep sample of lake water (No. 22) was more than that absorbed by the surface sample (No. 23) obviously because the latter sample at the time of collection had been in prolonged contact with the air. Where nitrates occur the

water of Lake Michigan contrasts very favourably with water supplied to London. This is strikingly illustrated in Table V, which contains the average analyses of two rivers of the London Supply (one river derived the water from deep wells) placed side by side with the analyses made in THE LANCET Laboratory of a sample of Lake Michigan water obtained at the intake marked 10 on the map. Thus, in respect of colour, total solid matter, hardness, chlorine and oxygen required to oxidise organic matter, the Michigan water is seen to be even superior to the choicest London's supply.

There is, however, one important difference which cannot be overlooked and that is that in all the samples of lake water there existed sedimental matter. The presence of water also was common to the lake samples with the exception of No. 10. This fact would have passed without comment if we did not know that the water is neither stored nor filtered, but distributed exactly as drawn from the lake. It is now known that careful filtration through beds of sand effects not only the complete purification of water from suspended matter, but, what is of greater importance, it removes also the existing organisms. As has been shown, the lake water contains low forms of vegetable life and also quantities of matter in suspension, and as these are likely to find their way to the mains the desirability of taking some precautionary measures of this kind is obvious. In consideration of these facts I counsel the public visiting Chicago to use nothing but boiled or filtered water in spite of the degree of purity which is indicated by chemical analysis. It is hardly possible now at the eleventh hour for the authorities to provide for the filtration of the Chicago supply on a large scale, but the water can be recently filtered as it leaves the tap. We need hardly insist here on the desirability of submitting all domestic waters to periodical cleansing, and, further, that their collection should be such as to provide in addition for the thorough impregnation of the water with air during filtration. Carelessness in the management of all domestic filters is worthy of strong condemnation, precautions of the very strictest order should be taken to ensure protection against the contamination of the water that may arise from the accumulation of filth in the pores. All filters should be so constructed that they may be submitted to the heat of boiling water for some time, in order that the filth and the organisms accumulated in their pores may be completely destroyed or removed. Boiling of the water wards off for certain many dangers, whilst it also renders the work of the filter considerably lighter, as by such treatment much of the solid matter dissolved in water is precipitated. Though boiling renders water insipid it renders it quite safe for drinking purposes and its palatability may be restored by adding, inasmuch as water at a low temperature is capable of taking increased quantities of air into solution.

In view of the excellent character so far as chemical analysis goes, of the water of Lake Michigan, which nature has placed, so to speak, at the very door of the city it is almost suicidal to run the risk that is now being run of seriously polluting so unlimited and pure a supply of water by the ugly dumping process, which consists in throwing Chicago's very worst refuse into its midst. That there is a better more rational, more wholesome and more effectual way by which it could be disposed of there can be little doubt. Indeed, the sewage and refuse of Chicago need never be discharged into the river in the raw and crude state in which it is evidently thrown into it now.

TABLE VII

Microscopical Examination of Sediment (Domestic Supply)

Sample No.	Observations.
5	Few micrococci, algae and mineral matter
23	Brown vegetable matter, few bacteria
29	Vegetable debris, plenty of bacteria, oxide of iron &c like lake samples.
30	Same as No. 29 desmids, bacteria &c.
31	Brown mineral and vegetable matter, hyphæ and few bacteria.
32	Paramoecia, bacteria, plant-tissue, desmids &c.
33	Few bacteria, micrococci, desmids, same as No. 29 dead water fleas.
34	Swarms of monads, and debris chiefly of vegetable kind.
25	Similar to No. 32 bacteria and plant tissue.
23	Ordinary pond water organisms, diatoms, few bacteria, infusoria &c.

DOMESTIC SUPPLY

Elsewhere it is stated that owing to the breaking of eight out of ten samples in the second case sent to THE LANCET offices, which contained specimens chiefly of the domestic supply to Chicago, our agent was instructed to repeat the collection of such samples. This was done, and a few weeks ago the case containing these new samples came to hand. Two bottles of the twelve contained in the case had unfortunately succumbed to the exigencies of travel. It is much to be regretted that one of these was a sample of water taken from a tank in the World's Fair grounds. The other was a sample of the ordinary supply to Chicago taken in a druggist's store in Sixty second street.

It is convenient to treat the samples of domestic supply separately and the results of analysis are therefore recorded in Table VI. In Table VII. will be found also the results of the microscopical examination of the deposits occurring in these waters. A comparison of the analytical results in this table, with the results recorded in Table I, which includes the river and lake samples, will show that the organic carbon and nitrogen were not estimated, the ammonia liberated on boiling the water with alkaline permanganate being introduced in their place. It was simply a matter of convenience to do so, as not only is the carbon and nitrogen process of Frankland very long and tedious, but a larger quantity of water than could well be spared is required to be operated upon. The albuminoid ammonia, as it is called, is, however, a reliable factor in that it serves to indicate the kind and, to an extent, the amount of pollution from certain sources.

A consideration of these results of analysis shows at once that two distinct classes of waters are being dealt with. To the first class belong Nos. 28, 29, 30, 32, 33, 35 and 36, and to the second Nos. 27, 31 and 34. The former are practically identical in composition with the lake samples, Nos. 10, 22, 23, Table I, the latter are derived from springs. The points from which all these samples were procured, are sufficiently described in Table VI. Neither is it considered necessary to indicate on the map the localities whence these samples came. The water supplied from the ordinary mains of the pumping stations may be considered first.

Ordinary supply—Attention has already been drawn to the desirability of filtering the lake water for drinking purposes. The necessity of adopting some precaution of this kind is again obvious when the above results are considered. Not a single sample of ordinary supply or lake-derived water was entirely free from sediment and the sediment in the majority of instances was found to consist of vegetable debris with numerous organisms, chiefly of the pond water kind.

In sample No. 33, which represents the water pumped by the North Side station supplied to the North Side residents, dead water fleas were found floating in the liquid. In fact in respect of suspended matter or deposit the water supplied in the mains is as was predicted, quite as unsatisfactory as the water taken from the lake. From another point of view indeed the samples are even more unsatisfactory. Take the measurement of colour for instance. Whilst the samples taken from the lake exhibit a remarkable freedom from brown colour, the highest being eight degrees and the other two being only four degrees the colour of water taken from the mains varied from nine to twenty-two degrees of brown and in one instance (No. 33 again) it was above the scale. This increase of brown tint is probably due to the waters having been in contact with the sediment which not improbably accumulates from time to time in the mains. Iron, again, would impart distinctive colour. We are therefore provoked to repeat our observations in regard to the necessity of filtration. The water supplied to Chicago from Lake Michigan is chemically satisfactory in all respects but one, it contains suspended matter. But with proper and efficient filtration there is nothing so far as its chemistry goes to suggest that the water supplied to the city is not well suited for all domestic and dietetic purposes. The residents of Chicago are evidently aware of the desirability of filtration, as it will be observed on inspection of the table that two of the samples (Nos. 23 and 35) had been filtered through Pasteur filters. In spite of this these samples were as bad as, if not worse than, the unfiltered water ordinarily supplied. On the face of it this may appear paradoxical, but the explanation of this seeming anomaly is not far to seek. It is customary in Chicago

oxygen required rapidly diminishes, in other words aeration and consequent purification have already been effected by natural operations. This is especially noticeable in the case of those river samples which have been mixed with the lake supply, to wit, Sample 3 near the river mouth and Sample 17 near the pumping station, Fullerton avenue.

There is little to remark about suspended matter, as what is recorded in the tables speaks sufficiently. It occurred to a slight extent in all the lake samples, whilst in one surface sample (No 23) there was sufficient to permit of estimation. Suspended matter in lake water was chiefly inorganic, whilst that from the river was largely organic.

INTERPRETATION OF RESULTS

The River—The disgusting condition of the Chicago River has been already made plain from the foregoing observations. With the exception of Samples 3 and 17, which practically consist, as has been shown, of lake water, the whole of the river samples exhibit a composition which in point of impurity vastly exceeds the limits in regard to liquids inadmissible into any stream laid down by the Rivers Pollution Commissioners. The extent of animal pollution in Group I is appalling. It is of the worst kind, animal refuse being indiscriminately mixed with common sewage. The pollution begins at the very mouth of the river and increases in intensity until a maximum is reached in the vicinity of the stockyards not far from the Southern Branch Pumping Station, where the filthy conditions are such as to defy description.

A glance at the temperature column of Table I will show that the temperature of the water varied from 33° F at the mouth to 44° F at the stockyards, whilst the air temperature was in no case higher than 24° F. It is safe to conclude, therefore, that the condition of the river in summer must be still more abominable.

A comparison of the analyses belonging to this group with the average sewage of towns in England is at once instructive and striking. The results are given in grains per gallon in Table IV.

The Chicago River at these points is even worse than crude sewage, and it is not surprising that the foul emanations and smells arising from the putrefaction of the animal offal and excreta which are evidently discharged into it in the raw state are described as vile, offensive and nauseating. Whether these smells sensibly affect the health of the neighbourhood is a question of importance to decide, the probability is that they do. No one will deny, however, that the existence of nauseating smells in the air is, in the interests of public health, very undesirable, and the inhalation of such offensive air, especially in times when epidemics are prevalent, should be avoided. It is reasonable to suppose further that air so contaminated is also germ laden.

Reference has already been made to the expedient by which a reverse current is induced in the Chicago River by means of pumps situated at the station marked Y on Map I. This arrangement, whilst it serves to maintain a current at the sluggish rate of one-third of a mile an hour and tends to some extent to replace the foul and dirty water of the river with pure lake water, can hardly be expected to affect the branch below Y, which serves the stockyards. The water here is probably quite stagnant, and filth must accumulate day by day.

At Points 6 and 7 on the Map—the latter from a canal immediately opposite 6—samples were taken which formed the members of Group II (see Diagram Map). These samples represent, therefore, the state of the water below the pumps. Doubtless the pollution of these waters is to a great extent due to the proximity of the branch which leads to the stockyards. Compared with the samples actually taken off the stockyards they are, as might be expected, somewhat less impure, but still of a repulsive character.

Turning to that part of the river which lies between the North and South fork and the pumping station marked Y on the map, we find that the impurities are further reduced. The samples obtained here belong, in fact, to Group III. They were all evidently polluted, but are waters in which the impurities have been attenuated by admixture with other water.

Next comes the northern branch of the river, which, it will be remembered, is swept by a current of lake water pumped into it at Fullerton avenue—the point marked X on the map—where powerful pumps discharge lake water into the river at an average rate of 10,000 gallons a minute. A sample (No 17) was obtained just below the station, and another (No 3) at the mouth of the river, both the samples exhibited the composition of lake water and are therefore included with the lake waters in Group IV, but, as might be anticipated, they

are in a slight degree less organically pure, being liable doubtless to contamination with river water. One interesting feature presented by these two waters is the amount of nitrates contained in them, which, as has been pointed out, would indicate oxidation of the nitrogen in organic matter effected by the introduction of fresh aerated lake water.

The Lake—In spite of the dumping process—that is, the discharge of sludge dredged up from the bed of the river into Lake Michigan—chemical analysis fails to furnish any distinct evidence that the lake is seriously polluted. It is well to bear in mind, however, that the sludge must consist to a large extent of insoluble matters, the greater part of the soluble constituents having been dissolved out probably into the river. The sludge would not contain any large amount of chlorides, for instance, for there would be a tendency for these to be washed out by the slow current which is induced to flow from the mouth of the river to the pumping station, but, on the other hand, it would be a matter of surprise if the sludge was free from phosphates, the greater proportion of which, being insoluble, would settle to the bottom of the river. Oddly enough, the lake samples contained distinct quantities of phosphates, but very little chlorine. We do not feel justified, however, in laying any particular stress upon this otherwise interesting observation, as it is quite possible that the presence of phosphate in the lake is, after all, a natural occurrence. There is no mention made, however, of the presence of phosphates in Chicago water in the following analysis made by Professor J W Mallet, F.R.S., in 1881. This analysis is interesting, in that the results show a remarkable agreement with those obtained recently in THE LANCET Laboratory. It certainly is remarkable, if it is not significant, that the chlorine, according to this analysis, was distinctly less ten years ago.

The following arrangement admits of an easy comparison between this analysis and that made recently in THE LANCET Laboratory—

Appearance	Chicago water	Lake water
	Analysis made in 1881.	Analysis made in 1893.
	Slightly turbid	Slightly turbid
Colour	Blue	Blue
Total solid	11.20	11.90
Chlorine	0.14	0.56
Organic carbon	0.098	0.120
Organic nitrogen	0.0217	0.021
Ratio C N	4.5 1	5.7 1
Ammonia	0.0066	0.0035
Nitrites	None	None
Nitrates	None	0.028
Oxygen required	0.028	0.028

The weights given represent grains per gallon.

It is certain, however, that if the lake were polluted to any serious extent it would contain much more chlorine and nitrogen in some form or other than was shown to be present according to the above analysis.

As a rule, the organic contamination of a lake is rapidly eliminated by atmospheric and other influences, light also being a potent factor, and whilst pollution may not exist, the presence of oxidised matter—e.g., nitrates—would to an extent indicate past contamination. Nitrates, however, were not found except in minute quantity. This fact cannot be accepted as trustworthy evidence in favour of the view of pollution not having taken place, since in lakes generally vegetation abounds and nitrates, it is well known, are rapidly absorbed by plant life.

Except for the presence of phosphates there is nothing contained in Samples 22 and 23 obtained over the dumping grounds in the lake, to indicate contamination from that source. Be it remarked, however, and it is satisfactory to note, that the intake sample (No 10) is a degree purer, chemically speaking, than the dumping ground samples referred to. It contained a measurable quantity of nitrogen as nitrates which were present only in traces in the water taken over the dumping grounds, the organic nitrogen was correspondingly lower, whilst the amount of oxygen required to oxidise organic matter was practically nil. In all these respects, indeed, the intake sample leaves little to be desired. Of the two dumping ground samples, the deep sample was a trifle less pure than that obtained at the surface, but the latter sample contained a notable quantity of suspended matter, which was probably floating on the top of the water at the time of collection.

The results of chemical analysis, therefore, lead us to the conclusion that the clear or filtered lake water is comparatively pure. It is of excellent quality and well adapted for both domestic and other ordinary purposes. In respect of organic purity,

the water of Lake Michigan contrasts very favourably with water supplied to London. This is strikingly illustrated in Lake V, which contains the average analyses of two waters of the London Supply (one river-derived the other from deep wells) placed side by side with the analyses made in THE LANCET Laboratory of a sample of Lake Michigan water obtained at the intake marked 10 on the map. Thus, in respect of colour, total solid matter hardness and oxygen required to oxidise organic matter the Michigan water is seen to be even superior to the choicest of London supply.

There is however one important difference which cannot be overlooked and that is that in all the samples of lake water there existed sedimental matter. The presence of water which was common to the lake samples with the exception of No. 10. This fact would have passed without comment were it not that the water is neither stored nor filtered, but is drawn exactly as drawn from the lake. It is now known that careful filtration through beds of sand effects not only the complete purification of water from suspended matter, but what is of greater importance it removes also all existing organisms. As has been shown, the lake water contains low forms of vegetable life and also quantities of matter in suspension, and as these are likely to find their way to the mains, the desirability of taking some precautionary measures of this kind is obvious. In consideration of these facts, would the public visiting Chicago to use nothing but boiled or filtered water in spite of the degree of purity which is attested by chemical analysis. It is hardly possible now at the seventh hour for the authorities to provide for the filtration of the Chicago supply on a large scale, but the water can be efficiently filtered as it leaves the tap. We need hardly say here on the desirability of submitting all domestic water to periodical cleansing, and, further, that their consumption should be such as to provide in addition for the thorough impregnation of the water with air during filtration. Carelessness in the management of all domestic filters is a source of strong condemnation, precautions of the very strictest should be taken to ensure protection against the contamination of the water that may arise from the accumulation of filth in the pores. All filters should be so constructed that they may be submitted to the heat of boiling water for some time in order that the filth and the organisms accumulated in their pores may be completely destroyed or removed. Boiling of the water wards off for certain many of the dangers whilst it also renders the work of the filter considerably lighter, as by such treatment much of the solid matter dissolved in water is precipitated. Though boiling renders water insipid it renders it quite safe for drinking purposes, and its palatability may be restored by adding as much as water at a low temperature is capable of taking increased quantities of air into solution.

In view of the excellent character so far as chemical analysis goes, of the water of Lake Michigan, which nature has placed so to speak, at the very door of the city it is suicidal to run the risk that is now being run of allowing polluting so unlimited and pure a supply of water by the right dumping process, which consists in throwing Chicago's very worst refuse into its midst. That there are other more rational, more wholesome and more effectual means by which it could be disposed of there can be little doubt. Indeed, the sewage and refuse of Chicago need never be discharged into the river in the raw and crude state in which it is evidently thrown into it now.

DOMESTIC SUPPLY

Fl-eewhere it is stated that owing to the breaking of eight out of ten samples in the second case sent to THE LANCET office, which contained specimens chiefly of the domestic supply to Chicago our agent was instructed to repeat the collection of such samples. This was done, and a few weeks ago the case containing these new samples came to hand. Two bottles of the twelve contained in the case had unfortunately succumbed to the exigencies of travel. It is much to be regretted that one of these was a sample of water taken from a tank in the World's Fair grounds. The other was a sample of the ordinary supply to Chicago taken in a druggist's store in Sixth second street.

It is convenient to treat the samples of domestic supply separately and the results of analysis are therefore recorded in Table VI. In Table VII will be found also the results of the microscopical examination of the deposits occurring in these waters. A comparison of the analytical results in this table, with those already recorded in Table I which includes the river and lake samples, will show that the organic carbon and nitrogen were not estimated, the ammonia liberated on boiling the water with alkaline permanganate being introduced in their place. It was simply a matter of convenience to do so, as not only is the carbon and nitrogen process of Frankland very long and tedious, but a larger quantity of water than could well be spared is required to be operated upon. The albuminoid ammonia as it is called is however a reliable factor in that it serves to indicate the kind and to an extent the amount of pollution from certain sources.

A consideration of these results of analysis shows at once that two distinct classes of waters are being dealt with. To the first class belong Nos. 28, 29, 30, 32, 33, 35 and 36, and to the second Nos. 27, 31 and 34. The former are practically identical in composition with the lake samples, Nos. 10, 22, 23, Table I, the latter are derived from springs. The points from which all these samples were procured, are sufficiently described in Table VI. Neither is it considered necessary to indicate on the map the localities whence these samples came. The water supplied from the ordinary mains of the pumping stations may be considered first.

Ordinary supply—Attention has already been drawn to the desirability of filtering the lake water for drinking purposes. The necessity of adopting some precaution of this kind is again obvious when the above results are considered. Not a single sample of ordinary supply or lake-derived water was entirely free from sediment, and the sediment in the majority of instances was found to consist of vegetable debris with numerous organisms chiefly of the pond water kind.

In sample No. 33, which represents the water pumped by the North Side station supplied to the North Side residents, dead water fleas were found floating in the liquid. In fact in respect of suspended matter or deposit the water supplied in the mains is as was predicted, quite as unsatisfactory as the water taken from the lake. From another point of view indeed the samples are even more unsatisfactory. Take the measurement of colour for instance. Whilst the samples taken from the lake exhibit a remarkable freedom from brown colour the highest being eight degrees and the other two being only four degrees, the colour of water taken from the mains varied from nine to twenty-two degrees of brown and in one instance (No. 33 again) it was above the scale. This increase of brown tint is probably due to the waters having been in contact with the sediment which not improbably accumulates from time to time in the mains. Iron, again, would impart distinctive colour. We are therefore provoked to repeat our observations in regard to the necessity of filtration. The water supplied to Chicago from Lake Michigan is chemically satisfactory in all respects but one, it contains suspended matter. But with proper and efficient filtration there is nothing so far as its chemistry goes, to suggest that the water supplied to the city is not well suited for all domestic and dietetic purposes. The residents of Chicago are evidently aware of the desirability of filtration, as it will be observed on inspection of the table that two of the samples (Nos. 28 and 36) had been filtered through Pasteur filters. In spite of this these samples were as bad as, if not worse than, the unfiltered water ordinarily supplied. On the face of it this may appear paradoxical but the explanation of this seeming anomaly is not far to seek. It is customary in Chicago

TABLE VII
Microscopical Examination of Sediment (Domestic Supply)

Sample No.	Observations.
27	Few micrococci, algae and mineral matter.
28	Brown vegetable matter, few bacteria.
29	Vegetable debris, plenty of bacteria, oxide of iron &c. like lake samples.
30	Same as No. 29, desmids, bacteria &c.
31	Brown mineral and vegetable matter, hyphæ and few bacteria.
32	Paramecia, bacteria, plant tissue, desmids &c.
33	Few bac.eria, micrococci, desmids, same as No. 29, dead water-fleas.
34	Swarms of monads, and debris chiefly of vegetable kind.
35	Similar to No. 32, bacteria and plant tissue.
36	Ordinary pond water organisms, diatoms, few bac.eria, infusoria &c.

expedient by which a reversed current is induced in the river by means of pumps situated at the station marked *y* on the map, which transfer the water into the Illinois Canal. These pumps are apparently effective to the extent of preventing the flow into the lake of the very foul water which accumulates from the stockyards and other sources of pollution in the southern branch of the river. The northern branch of the river is swept by a stream pumped into it at Fullerton avenue—the point marked *x* on the map—where powerful pumps discharge lake water into the river at an average rate of 10,000 gallons a minute. Operations are in progress at the present time for superseding the canal pumping station *y* by means of a deepened channel cut across the high ground intervening between the city of Chicago and the slope drained by the Illinois River. This trench when completed will afford a bed upon which the water of the Chicago will gravitate down into the Illinois River, and will doubtless prove much more efficient than the present arrangement, but this work is not expected to be complete before the year 1895, and therefore, although a matter of prime importance to dwellers in Chicago, is of no significance whatever from our present point of view.

With regard to the disposal of the Chicago River sludge greater difficulties arise. In the first place, the dredging operations are not conducted upon any systematic plan. A certain amount of dredging is done by the urban authorities, but this is, we believe, confined to certain spots in the river, such, for example, as the waterway under bridges and the like. Much of the dredging is done by private enterprise, and it is of course difficult in those circumstances to enforce the strict observance of even the most necessary precautions. Steps have, we believe, been recently taken to secure a better control of the dredging work and especially to enforce the observance of the rules as to the selection of dumping grounds and the avoidance of other parts of the lake than those officially designated for this purpose. From the map (No I), in which the dumping grounds are shown, it will be seen that they are situated within two miles of the intake marked D. This proximity is probably to be accounted for by the fact that the dumping ground was selected long before the crib and its tunnel, which are the latest additions to the waterworks of Chicago, were designed. Whether it is intended, or indeed possible, to use other dumping grounds in future, we do not know. The inconvenience and even peril of the arrangement shown cannot possibly have escaped the notice of the city authorities, and it is probable that when public attention has been called to the matter they will be able to make reassuring announcements upon the subject.

Another danger and one of a peculiarly insidious character resulting from the imperfect dredging of the Chicago River must be kept in view in this inquiry. An enormous shipping traffic has sprung up upon the American lakes, which has converted Chicago into one of the five or six largest ports in the world. The craft carrying on this traffic find great inconvenience in navigating the river through the silting up of its channel, and it seems impossible to doubt that they carry river mud adhering to their bottoms far out into the lake. This, though not a source of pollution on any considerable scale, might easily become the means of occasional infection of the water supply.

The southern system, like the northern, is represented by a single pumping station, marked VI upon the map. Its intake is marked B, and situate about one mile from the shore, with which it is connected by a tunnel of six feet diameter. The single station is equipped with very powerful pumping machinery, to which an addition has recently been made of pumps which will deliver 24,000,000 gallons daily, this being the estimated requirement for the special purposes of the Exhibition. This intake is exposed to contamination both from the south shore sewers and the Calumet River, and its position is, we believe, considered by the city authorities to be for this reason unsatisfactory. Such as it is, however, it is the source from which must be derived the water to be supplied in Jackson park and the entire southern district of Chicago. This, therefore, is, next to the central supply, that which most nearly concerns visitors to the Exhibition. Within the Exhibition grounds the lake supply will be supplemented by an entirely independent service of spring water provided by the Waukesha Hygeia Mineral Spring Company, which has laid extensive water mains for distributing, and has connected its spring at Waukesha with the Exhibition grounds by something like 116 miles of water pipe. This water is to be sold at one cent a glass.

APPENDIX II.

The following letters have been kindly forwarded to the Mayor of Chicago as comprising a full statement of systems of drainage and water supply of the city of Chicago together with the observations of the medical officer of health upon the sanitary condition of the city—

Department of Public Works, March 2nd, 1891

E. Louis Kuhns, Esq., Commissioner

DEAR SIR,—Complying with your request of Feb 20th pencilled memorandum thereon, I beg to present a general report of the water resources of the city of Chicago, together with an outline map showing pump stations, tunnels, cribs, referring also to contemplated improvements.

The total pumpage for 1892 was 71,035,462,221 gallons average of 195,000,000 gallons per day, distributed thru the mains as potable water by means of seven pump stations—

1 Lake View	5 West Side.
2 North Side	6 Sixty eighth street
3 Central	7 Washington Heights
4 Fourteenth street	

1 *Lake View*—Located at the corner of Sulzer avenue Halstead street, containing the following engines—

Style	Date	Capacity
Gaskill horizontal	1892	12,000 (
"	1886	12,000 (
Worthington horizontal	1882	5,000 (
Flanders "	1892	2,000 (

Daily capacity 31,000 (

This station is fed by a 6 ft. brick tunnel, the temporary intake of which, now in use, is at a distance of 6500 ft., the permanent intake of which, to be opened during summer of 1893, will be at a distance of 10,000 ft. shore. It is contemplated to have in the north west part of the city another large pumping station, to be connected with the lake by means of a land tunnel joined to existing lake tunnel system opposite Chicago avenue.

2. *North Side*—Located at the intersection of Chicago avenue and Pine street, containing the following engines

Style.	Date.	Capacity
Pittsburg double beam	1872	36,000 (
"	1867	18,000 (
Gaskill, two double horizontal	1886	24,000 (
" single beam	1857	12,000 (
" "	1853	8,000 (

Daily capacity 98,000 (

The two last-named engines are not very often used and it is the intention to install in their place in the future more powerful and modern engines. This station derives its water from the original crib two miles out in the lake, connexion being two brick tunnels 5 ft. and 7 ft. respect in diameter. There is also an emergency tunnel 7 ft diameter leading to a new crib on the north west end of outer Government breakwater.

3. *Central*—Located on Harrison street, between Harrison and Desplaines streets, completed in 1891 and containing the following engines—

Style.	Date	Capacity
Allis triple expansion	1891	18,000 (
" "	1891	18,000 (

Daily capacity 36,000 (

This station is connected both with the land tunnel, 7 ft diameter, leading to the West Side station and with the land tunnel, which is a ramification of the new four lake tunnel described subsequently.

4. *Fourteenth street*—Located at the corner of Fourteenth street and Indiana avenue in 1891, deriving its water from the New Four mile Tunnel through an 8-ft. land ramification but also connected with the old 7 ft. land tunnel by means of a tunnel tapering from 5 ft. to 2½ ft. on Desplaines street and a 6-ft. tunnel on Jefferson street, and containing the following engines—

Style.	Date	Capacity in ga
Allis triple expansion	1892	18,000 (
" "	"	18,000 (
" "	"	18,000 (

Daily capacity 54,000 (

remains for another engine of at least the same as the present one which should be arranged for as possible.

Side—Located at the intersection of Ashland and Erie Island avenue, completed in its first half in 1882 containing the following engines—

Style	Date	Capacity in gallons.
Beam Corliss	1876	30 000 000
"	1893	30 000 000

Daily capacity .. 60 000 000

draws water from the original two-mile crib by means of a siphon across the town of the 7 ft. brick tunnel above as feeding the North Side station.

Sixty-eighth street—Located at the corner of Sixty-eighth and Oglesby avenue, whence a 36-in. water main has been laid to supply water to the World's Columbian Exposition, which will be an independent and direct connection with two new Gaskill engines of 12,000 000 gallons each, thus being enabled to send the entire output to Exposition grounds if needed. This station now contains the following engines—

Style	Date	Capacity in gallons.
McAllister	1892	6,000 000
McAll ..	1886	12,000 000
"	1888	12,000 000
"	1892	12,000 000
"	1892	12,000 000
Washington	1890	12,000 000
McAll vertical	1881	8,000 000
McAll	1878	3,000 000

Daily capacity 77,000 000

proposed to do away as soon as possible with the 30,000 000 gallons Cape-Maxwell, the 8,000 000 Holly vertical and 30,000 000 Knowlton all of which are out of date, out of repair and expensive in operation and to replace them with a single high-duty modern pumping engine of about 100 000 000 gallons capacity. This station is fed by a 6 ft. lake at Sixty-eighth street, details of which are given in the heading "Tunnels."

Washington Heights—Located on Vincennes avenue, One Hundred and Fourth street, and deriving its water from an Artesian well of a daily capacity of 500 000 gallons.

PUMPING PLANTS FOR CLEANING THE CHICAGO RIVER.

Fullerton-avenue Station, of a capacity of about 20 cubic feet per minute, erected in 1879 at Fullerton and the north branch of the Chicago River for the purpose of flushing the latter draws fresh water from the river through an intake off Fullerton avenue and a cross town tunnel and houses a vertical engine with horizontal bearings two propeller wheels which force the lake water the river against a head of about 2 ft., and thus creates a current in the north branch towards the junction with the river and thence down the south branch towards the Fullerton station.

Canal Pumping Station, located at Ashland avenue and Illinois and Michigan Canal, was erected in 1882 for the purpose of lifting the contents of the Chicago River into Illinois and Michigan Canal at the rate of 60,000 cubic feet per minute. It houses four sets of centrifugal pumps of initial capacity of 15,000 cubic feet per minute each, there now being exchanged gradually for four sets of lifting pumps of a contract capacity of 25,000 cubic feet per minute each against a head of 6 ft., under a contract with Centwright Hydraulic Machinery Company. The term of completion is July 8th, 1893, so there would be a capacity of 100 000 cubic feet per minute from that day on.

TUNNELS.

these there are four systems—

1. Lake View
2. Two Mile.
3. Four Mile.
4. Sixty-eighth street.

Lake View—Mentioned under the heading of Lake View Pump Station. This is a 6 ft. tunnel, and has a capacity of 100,000 gallons per twenty four hours.

Two Mile—The tunnels terminating at the two-mile crib have a diameter of 5 ft. and 7 ft. respectively as mentioned above, and an aggregate daily capacity of 158,000 000 gallons. If the shore gate of the 7 ft. inlet tunnel terminated at the exterior Government breakwater (see under

North Side Pumping Station) were to be opened fully, the aggregate capacity would be upwards of 220,000,000 gallons, one-half of which would be furnished by the short emergency tunnel. This has never been done. It is contemplated to extend this 7 ft. shore inlet tunnel to the two-mile crib, join it with the 5 ft. and 7 ft. tunnels terminating there into a single 13 ft. or a double 10 ft. tunnel, and extend the system thus simplified to a point four and a half miles from shore, where a new intake would be constructed. The capacity of this system would be 270,000 000 gallons per twenty four hours.

3. Four Mile—The new four mile tunnel, which was completed in November, 1892, has a diameter of 8 ft. and a daily capacity of 140 000,000 gallons. The new pumping stations on Fourteenth and Harrison street's derive their water from this tunnel, as mentioned above.

4. Sixty-eighth street—This tunnel has its present (submerged) intake one mile from shore, a diameter of 6 ft. and a capacity of 72,000 000 gallons. For the purpose of improving the quality of the flow it is being extended as a 7 ft. tunnel to a point two miles from shore under a contract with Messrs. Lydon and Drew of this city, which sets the date of completion of the new work and of filling the extended tunnel with water from the new intake at Feb 20th, 1893. The city intends to establish, in addition to the two cribs and shafts with three working faces provided in the contract, two more cribs and shafts increasing the number of working faces to seven, and thus expects to pump water from the new intake by July 1st 1893. The quantity of the flow is not altered by the extension.

SUMMARY OF PRESENT CAPACITIES.

I.—Pumping Stations

	Gallons.
1. Lake View	31,000 000
2. North Side	93,000 000
3. Central	36 000 000
4. Fourteenth street	54 000 000
5. West Side	60,000 000
6. Sixty-eighth street	77 000 000
7. Washington Heights (Artesian well)	500,000

Total capacity for twenty-four hours 356 500 000

II.—Tunnels

	Gallons.
1. Lake View	72,000 000
2. Chicago avenue	220,000 000
3. Four Mile	140 000 000
4. Sixty-eighth street	72,000 000

Total capacity for twenty-four hours 504 000 000

Outline map enclosed.*

Yours truly

DION GERALDINE, City Engineer

Department of Public Works March 2nd 1893.

E. Louis Kahns Esq. Commissioner

DEAR SIR,—I beg to supplement my report of this morning with the following relative to the sewage of the city:—About 85 per cent. of the entire sewage of the city is discharged into the Chicago River thence by the agency of the Canal Pump Works through the Illinois and Michigan Canal into the Desplaines River and thence into the Mississippi.

Yours truly

DION GERALDINE, City Engineer

Department of Public Works, March 4th, 1893.

E. Louis Kahns, Esq., Commissioner

DEAR SIR,—Eighty five per cent. (85 per cent.) of the total sewage of the city and especially the whole of the sewage of the business and manufacturing parts of the old city, is discharged into the various branches of the Chicago River and indirectly by means of the Bridgeport Canal pumping station, aided by the Fullerton-avenue flushing station, both of them described above into the Illinois and Michigan Canal, thence into the Desplaines River thence into the Illinois River, thence into the Mississippi River.

By far the greater portion of the remaining 15 per cent. of the total sewage of the city is furnished by districts devoted exclusively to residence and park purposes and is discharged directly into Lake Michigan through the following

* The data of this map have been incorporated in Map II.—En. L.

sewer outfalls, distributed along shore line twenty miles in length —

	Feet in Diameter		Feet in Diameter
<i>Lake View</i>		<i>Old City</i>	
Grand avenue Sewer	4	Twelfth street	5
Bryn Mawr	4	Twenty second street	6
North Fifty ninth street	4	Thirty fifth street	6
Lawrence-avenue	4	<i>Hyde Park</i>	
Graceland avenue	2	Forty first-street	4
Grace street	3	Forty third street	2½
Roscoe street	3	Forty fifth street	4
Belmont-avenue	2½	Fifty first-street	5
Surf-street	3	Fifty third street	2½
		Fifty sixth street	4½

A very small portion of the 15 per cent of the total is furnished by the manufacturing district in the Calumet basin and is discharged into the Calumet River, whence it cannot pass in its crude condition into Lake Michigan except in time of flood. The following are the sewer outfalls of this district —

Strand	5 feet	Ninety fifth street	4 feet
South Chicago-avenue	5 "		

The board of trustees of the sanitary district of Chicago are now constructing, under authority of an Act of the Legislature of the State of Illinois, a combined drainage channel and navigable water way of very large dimensions, which, when completed, will carry a *gravity flood of 600,000 cubic feet per minute* from Lake Michigan through the Chicago River, and eventually, it is expected, through the Calumet River also into the Desplaines, Illinois and Mississippi Rivers, superseding the present Illinois and Michigan Canal. It is intended to carry intercepting sewers along the lake shore and to discharge them into the river flow away from the lake. In this manner Lake Michigan will be protected absolutely and at all times against the entrance of any sewage from the city of Chicago.

Yours truly,

DION GERALDINI, City Engineer

Department of Health, City of Chicago, March 7th, 1893.

To His Honour the Mayor

I have the honour to report, in pursuance to your request for information concerning the supply of water, quality &c., that never before in the history of Chicago, population considered, have there been as few deaths as during the past fourteen months.

A year ago I caused to be made an examination of each case of typhoid fever reported where death resulted, and of the four hundred and over there were less than 5 per cent. of the cases where the attending physician ascribed the cause of death to the water supply. In many instances the patients were newcomers and had not become acclimatised, and it is possible and probable that they were more susceptible than they would have been under other circumstances. This may in a measure have accounted for the increased number of deaths during some portions of the winter of 1891-92 and should not properly be attributed to the water supply of the city. At intervals during the past two years analyses of the water have been made, and with few exceptions—and then under conditions of wind and weather that made it not a fair test—the quality has been equal, if not superior, to that of any of the large cities of the world. The conditions that now exist are sure to gratify the expectations of the most sanguine so far as an ample supply of pure and wholesome water is concerned.

As will be seen in the report of the city engineer 85 per cent. of the sewage of the city runs into the Chicago River and by means of pumps is transferred to the canal and thence out of the city, the very small proportion of sewage remaining which flows into the lake is at remote points from the intakes of the tunnels. The tunnels being situated two and four miles from shore makes it almost an impossibility, from their positions in the lake, to admit of any contaminations to the water supply.

I readily appreciate the importance of this question to those who are contemplating a visit to this city during the World's Fair and assure you that, judging from the results of the analyses, the conditions which surround the procuring of water would lead me to believe from a medical standpoint that, unless some unforeseen accident should arise, our thousands of visitors will have no cause for complaint at the quality of water furnished.

I have the honour to be respectfully yours,

JOHN D WARE, M.D.,
Commissioner of Health.

Deaths from Typhoid Fever during the years 1890, 1891 and January and February, 1893

Total deaths	21,856	27,754	26,219
Percentage of deaths from typhoid fever	4.61	7.19	5.67

The following letter, under date March 21st, 1893, been received direct from Dr Ware

DEAR SIR,—Your letter of March 8th to his Honour Mr Washburne has been forwarded to me. The contents have been noted. In reply, will say had it not been for sick I should have forwarded a reply before this date. I did see the report that was forwarded to you some days since his Honour, but I am assured that the plans &c. contained that report were absolutely correct, and in addition to the forward you to day two reports of analyses of the drink water supplied to the city of Chicago, under date of Jan. 1 and March 16th. These analyses were made from water as it drawn from the hydrants and not taken from out in the lake. The analyses shown were made by Professor Walter S. Hall and it would seem there is very little to complain of in character of our drinking water, notwithstanding so many adverse criticisms to the contrary. I trust that these may in time be included in former statements sent you.

I have the honour to be, Sir, respectfully yours,

JOHN D WARE, Commissioner of Health

APPENDIX III.

COLLECTION OF SAMPLES

The following instructions were issued to our agent in accordance with the guidance in the collection of samples. His report upon the operations and the log which he compiled of the expedition are also appended.

INSTRUCTIONS FOR MANIPULATING THE SAMPLE BOTTLES AND TAKING SAMPLES.

The cases will be found to be perfectly easy to open, being opened only with screws. The inner case may if necessary be withdrawn from the outer by means of the handles upon its lid, before the lid is unscrewed, but probably it will not be necessary to withdraw it.

The bottles are numbered 1 to 24 and an accompanying paper gives the particulars concerning the taking of the samples which are required. The particulars may be conveniently entered in a small notebook and arranged in the form shown in the margin hereof. If through inconvenient surroundings any of the original notes should be illegible or difficult to read, an explanation may with advantage be added but no attempt should be made to use ink or otherwise convert them into anything but rough notes.

A sinker accompanies the bottles which may be used in the following manner. The bottle is introduced into the tin holder and made fast therein by means of the wire strap which passes over its shoulder. The glass stopper is then to be withdrawn and the cork stopper substituted in its place. The weight must next be attached to the bottom of the tin holder and the whole sunk to the required depth as indicated by the metal tabs upon the suspending cord. This done, a pull upon the stopper-cord will draw the cork and the bottle will fill. The bottle is then to be drawn gently up to the surface and the glass stopper introduced whilst the neck is still immersed. The bottle may then be taken out of the water and the stopper tightened in its place, after which it should be immediately tied up with string. When a convenient stopping place is reached the parchment caps must be placed over the stoppers, the stoppers tied with the string sealed. The caps are to be made lissom by soaking them in water for a few minutes before use.

For return the covers of the cases may be placed clean and the address stencilled on in place of that at present upon them. For the benefit of our readers we give above a drawing of the taking apparatus.

REPORT ON THE COLLECTION OF SAMPLES OF LAKE MICHIGAN AND CHICAGO RIVER WATERS.

On Saturday, December 10th, 1892, at 8 A.M., I started to go to Dunham's 210 South Water street. I had previously placed twenty of the bottles received from the LANCET Offices in the wagon, and I rode down to Dunham's with them. Immediately upon arrival there I was introduced to Captain William Smith, who was directed to accompany me on my expedition and to lend me every assistance in his power to enable me to take, as carefully as possible, the samples of Lake and Chicago River water. I was instructed to collect. I was on board the *Bob Tied* at 9 A.M., and as there was but a slight wind blowing the captain deemed it advisable to proceed at once out on the lake.

Our first stoppage was at a distance of two miles off the Court House. When the tug was at a complete standstill Captain Smith assisted me in taking samples of the water of Lake Michigan, at a depth of six feet below the surface and

also at the surface. Both operations were carried out according to instructions received from you. In my notebook you will find details as to the temperature of the water and also of the air and the result of other observations you requested me to make. These notes were written down as each sample was withdrawn from the water, and no alteration whatsoever has been made to them. Our next stoppage was at four miles off the Court House, where I took two samples of Lake water—the first at six feet below the surface and the second at the surface—adhering strictly to your instructions and duly noting my observations in the book I am forwarding to you.

I took two more samples of the Lake water at a distance of five miles from the Court House, near the dumping grounds. These samples were taken at the surface and at a depth of twelve feet. The details are in the notebook.

I may here remark that Captain Smith is one of the most capable pilots on Lake Michigan and that he has been navigating that lake for the last fifteen years. His estimates of distances may therefore be assumed as absolutely correct. Personally, I was guided by the Two Mile Crib and the Four Mile Crib, and I feel perfectly convinced that we stopped at two, four and five miles respectively off the Court House.

The operations on Lake Michigan were then terminated, and we made headway for the river. Our first stoppage was at Wabash and Rush (Rush street bridge), where one sample of Chicago River water was taken at two feet below the surface. As each sample was withdrawn from the water I fixed the glass stopper firmly and placed a label on the bottle with its number, which number corresponded with a page in my notebook, so that no error was possible. Each bottle furthermore was carefully replaced in the box in which I had taken the bottles aboard the tug and, to ensure against possible mistakes, I inscribed on the box itself near the corner in which each bottle was placed, the number of the label. When I returned to my rooms I wrote out another set of labels with pen and ink and placed them on their respective bottles, after which I covered the stoppers with parchment and tied them up firmly. Finally I sealed all the bottles, and with them have returned to you the thermometers employed, my note-book and the seal employed by me.

After Rush-street-bridge the next sample was taken in mid stream, where the Chicago River branches off north and south, at a depth of two feet below the surface. We then proceeded up the north branch of the Chicago River taking a sample at Putnam and Robert's streets—that is to say, at Erie-street-bridge—at one foot below the surface. The bridge at Fullerton avenue being open, we passed through and proceeded half a mile above Fullerton avenue (Map L.) where we took a sample at one foot below the surface. The next sample was taken immediately below Fullerton avenue at one foot below the surface.

These collections terminated our expedition on the north branch of the river. We returned towards the spot where the river branches off north and south and then proceeded up the south branch. To gain time, and so as to complete all sample-taking before it became too dark, the captain deemed it advisable to proceed at once to the stock-yards and collect samples on our return journey.

It was a long trip up the south branch, and the bridges somewhat delayed us. However about 1.30 P.M. we were able to collect a sample on the East Fork, close to the stock-yards at two feet below the surface, another at two miles above the Pumping works south branch, one foot below the surface, another in the canal off Bridgeport, another off A. canal, another abreast of Joliet Steel Works (one mile above Fuller street), one at Fuller street and Rost-street, one off Dupont's Ship, and, lastly, one opposite the Union depot. All these samples were taken with the greatest possible care, and all observations about each one duly noted in the book forwarded to you.

We arrived at our landing-place opposite Dunham's (E 3) corner of Wells-street and the river—Dunham's being at the corner of South Water street and Fifth-avenue (Wells-street is the continuation of Fifth avenue on the north side). We disembarked here, it being more convenient for carrying off our samples. The wagon that conducted me to Dunham's in the morning met me, as agreed, at 3 P.M. and took the bottles back to my rooms where I added a second label, so that no possible error could arise as to identification. After
